## Invertibility
- PV-thinking in the real atmosphere
- The dynamical tropopause
- PV anomalies
- Upper level PV anomalies
- Low-level and surface PV anomalies
- Interaction of anomalies
- PV on isentropic maps

## The vorticity equation
- Cartesian coordinate form
- Scale analysis of the vorticity equation

## Vorticity in barotropic fluids
- The barotropic (Rossby) potential vorticity equation
- The barotropic vorticity equation
Pressure as a vertical coordinate

Transformation of the horizontal pressure gradient force from height to pressure coordinates:

\[
\frac{(p_0 + \delta p) - p_0}{\delta z} = \frac{(p_0 + \delta p) - p_0}{\delta z} \left( \frac{\delta z}{\delta x} \right)_p
\]

Limit as \( \delta z \to 0 \):

\[
\frac{(p_0 + \delta p) - p_0}{\delta z} \to -\left( \frac{\partial p}{\partial z} \right)_x
\]

Limit as \( \delta x \to 0 \):

\[
\frac{(p_0 + \delta p) - p_0}{\delta x} \to \left( \frac{\partial p}{\partial x} \right)_z
\]

\[
\therefore \left( \frac{\partial p}{\partial x} \right)_z = -\left( \frac{\partial p}{\partial z} \right)_x \left( \frac{\partial z}{\partial x} \right)_p
\]

Hydrostatic equation: \( \frac{\partial p}{\partial z} = -\rho g \)

\[
\therefore \left( \frac{\partial p}{\partial x} \right)_z = -(-\rho g) \left( \frac{\partial z}{\partial x} \right)_p
\]
\[ -\frac{1}{\rho} \left( \frac{\partial p}{\partial x} \right)_z = -g \left( \frac{\partial z}{\partial x} \right)_p \]

Recall the geopotential

\[ \Phi = \int_0^z gdz \implies \partial \Phi = g \partial z \]

\[ \therefore -\frac{1}{\rho} \left( \frac{\partial p}{\partial x} \right)_z = -\left( \frac{\partial \Phi}{\partial x} \right)_p \]

**Isobaric:** Characterised by equal or constant pressure, with respect to either space or time.

\[ -\frac{1}{\rho} \left( \frac{\partial p}{\partial x} \right)_z = -\left( \frac{\partial \Phi}{\partial x} \right)_p \quad (1.25) \]

and

\[ -\frac{1}{\rho} \left( \frac{\partial p}{\partial y} \right)_z = -\left( \frac{\partial \Phi}{\partial y} \right)_p \quad (1.26) \]

\[ \implies \text{In the isobaric coordinate system, the horizontal pressure gradient force is measured by the gradient of geopotential at constant pressure.} \]

Advantage of isobaric system: density is not explicit in the pressure gradient force.

**Note:**

\[ -\frac{1}{\rho} \left( \frac{\partial p}{\partial x} \right)_z - \frac{1}{\rho} \left( \frac{\partial p}{\partial y} \right)_z = -\frac{1}{\rho} \nabla_z p \]

\[ -\left( \frac{\partial \Phi}{\partial x} \right)_p - \left( \frac{\partial \Phi}{\partial y} \right)_p = -\nabla_p \Phi \]
A generalized vertical coordinate

Aim: To obtain a general expression for the horizontal pressure gradient; which is applicable to any vertical coordinate \( s = s(x, y, z, t) \)

Gradient: \( \frac{P_C - P_B}{\delta x} \)

\[
\begin{align*}
\frac{P_C - P_B}{\delta x} &= \frac{P_C - P_B}{\delta z} \frac{\delta z}{\delta x} \\
\frac{P_C - P_B - P_A}{\delta x} &= \frac{P_C - P_B}{\delta z} \frac{\delta z}{\delta x} - \frac{P_A}{\delta x} \\
\frac{P_C - P_B - P_A}{\delta x} &= \frac{P_C - P_B}{\delta z} \frac{\delta z}{\delta x} - \frac{P_A}{\delta x} \\
\frac{P_C - P_A}{\delta x} &= \frac{P_C - P_B}{\delta z} \frac{\delta z}{\delta x} + \frac{P_B - P_A}{\delta x}
\end{align*}
\]
$P_C - P_A$ : along diagonal where $s$ is constant

$\frac{\delta z}{\delta x}$ : its diagonal is constant $s$

$P_B - P_A$ : along $x$ where $z$ is constant

Taking the limits as $\delta x, \delta z \to 0$

$$\implies \left( \frac{\partial p}{\partial x} \right)_s = \frac{\partial p}{\partial z} \left( \frac{\partial z}{\partial x} \right)_s + \left( \frac{\partial p}{\partial x} \right)_z$$

(1.27)

Identity: $\frac{\partial p}{\partial z} = \left( \frac{\partial s}{\partial z} \right) \left( \frac{\partial p}{\partial s} \right)$

$$\therefore \left( \frac{\partial p}{\partial x} \right)_s = \left( \frac{\partial s}{\partial z} \right) \left( \frac{\partial p}{\partial s} \right) \left( \frac{\partial z}{\partial x} \right)_s + \left( \frac{\partial p}{\partial x} \right)_z$$

$$= \left( \frac{\partial p}{\partial x} \right)_z + \frac{\partial s}{\partial z} \left( \frac{\partial z}{\partial x} \right)_s \left( \frac{\partial p}{\partial s} \right)$$

(1.28)
Basic equations in isobaric coordinates

The horizontal momentum equation

\[
\frac{Du}{Dt} - fv = -\frac{1}{\rho} \frac{\partial p}{\partial x} \tag{2.24}
\]
\[
\frac{Dv}{Dt} + fu = -\frac{1}{\rho} \frac{\partial p}{\partial y} \tag{2.25}
\]

In vertical form:

\[
\frac{D\mathbf{V}}{Dt} + f \mathbf{k} \times \mathbf{V} = -\frac{1}{\rho} \nabla p \tag{3.1}
\]

where \( \mathbf{V} = iu + jv \) is the horizontal velocity.

From page 2:

\[-\frac{1}{\rho} \left( \frac{\partial p}{\partial x} \right)_z = -\left( \frac{\partial \Phi}{\partial x} \right) \quad \text{and} \quad -\frac{1}{\rho} \left( \frac{\partial p}{\partial y} \right)_z = -\left( \frac{\partial \Phi}{\partial y} \right) \]

\[
\frac{D\mathbf{V}}{Dt} + f \mathbf{k} \times \mathbf{V} = -\nabla_p \Phi \quad (\delta p < 0)
\]

\( \nabla_p \): horizontal gradient operator (\( p \) held constant)

\[
\frac{D}{Dt} = \frac{\partial}{\partial t} + \frac{Dx}{Dt} \frac{\partial}{\partial x} + \frac{Dy}{Dt} \frac{\partial}{\partial y} + \frac{Dp}{Dt} \frac{\partial}{\partial p} = \frac{\partial}{\partial t} + u \frac{\partial}{\partial x} + v \frac{\partial}{\partial y} + \omega \frac{\partial}{\partial p}
\]

where \( \omega = \frac{Dp}{Dt} \) is the “omega” vertical motion, the pressure change following the motion.

Geostrophic wind

\( \nabla_g = iu_g + jv_g \)

Vectorial form of the geostrophic wind:

\[
\nabla_g = \mathbf{k} \times \frac{1}{\rho f} \nabla p
\]
\[ f\vec{V}_g = \vec{k} \times \frac{1}{\rho} \nabla p \]

\[ \left( -\frac{1}{\rho} \delta p = g \delta z = \delta \Phi \right) \]

\[ = \vec{k} \times \nabla_p \Phi \]

No density term!

(3.4)

Thus, a given geopotential gradient implies the same geostrophic wind at any height.

... a given horizontal pressure gradient implies different geostrophic wind values depending on the density.

**Exercise:** The definition of the geostrophic wind in vector form is

\[ f\vec{V}_g = \vec{k} \times \nabla_p \Phi \]

Derive the divergence of the geostrophic wind for BOTH a constant and variable definition of the Coriolis parameter. For a variable Coriolis parameter, first show that

\[ \nabla \cdot \vec{V}_g = -\beta \frac{f}{f_g} v_g, \]

then consider

\[ \frac{\delta \phi}{\delta y} \delta y \]

where \( a (= R_E) \) is the radius of the Earth, \( \phi \) is the latitude and \( y \) the length along a latitude circle, to show that for a variable Coriolis parameter the divergence of geostrophic wind is equal to

\[ -v_g \frac{\cot \phi}{R_E} \]

**Solution:**

For constant Coriolis parameter:

\[ f\vec{V}_g = \vec{k} \times \nabla \Phi \]

\[ \nabla \cdot (f\vec{V}_g) = \nabla \cdot \left( \vec{k} \times \left( \frac{\partial}{\partial x} \vec{i} + \frac{\partial}{\partial y} \vec{j} \right) \Phi \right) \]

\[ f\nabla \cdot \vec{V}_g = \nabla \cdot \left( \frac{\partial}{\partial x} \vec{i} - \frac{\partial}{\partial y} \vec{j} \right) \Phi \]

\[ = \left( \frac{\partial}{\partial x} \vec{i} + \frac{\partial}{\partial y} \vec{j} \right) \cdot \left( -\frac{\partial}{\partial y} \vec{i} + \frac{\partial}{\partial x} \vec{j} \right) \Phi \]

\[ = \left( \frac{\partial^2}{\partial x \partial y} + \frac{\partial^2}{\partial y \partial x} \right) \Phi \]

\[ \therefore \nabla \cdot \vec{V}_g = 0 \]
For variable Coriolis parameter:

We have shown above that $\nabla \cdot \left[ k \times \nabla \Phi \right] = 0$

\[
\nabla \cdot (f \vec{V}) = 0
\]

\[
\therefore \nabla \cdot (f u_g \vec{i} + f v_g \vec{j}) = 0
\]

\[
\therefore \left( \frac{\partial}{\partial x} (f u_g \vec{i}) + \frac{\partial}{\partial y} (f v_g \vec{j}) \right) = 0
\]

\[
\therefore \frac{\partial}{\partial x} (f u_g) + \frac{\partial}{\partial y} (f v_g) = 0
\]

\[
\therefore \frac{\partial}{\partial x} (f u_g) + f \frac{\partial u_g}{\partial x} + \frac{\partial f}{\partial y} v_g + f \frac{\partial v_g}{\partial y} = 0
\]

\[
\therefore f \left( \frac{\partial u_g}{\partial x} + \frac{\partial v_g}{\partial y} \right) = -\frac{\partial f}{\partial y} v_g
\]

\[
\therefore \nabla \cdot \vec{V}_g = -\beta v_g
\]

\[
\therefore \nabla \cdot \vec{V} = -\beta \vec{V}
\]

From the figure

\[
\delta y = a \delta \phi
\]

\[
\therefore \frac{1}{\delta y} = \frac{1}{a} \frac{1}{\delta \phi}
\]

\[
\beta = \frac{\partial f}{\partial y}
\]

\[
= \frac{1}{a} \frac{\partial f}{\partial \phi}
\]

\[
= \frac{1}{a} \frac{\partial}{\partial \phi} (2\Omega \sin \phi)
\]

\[
= \frac{2\Omega}{a} \cos \phi
\]

\[
\therefore \nabla \cdot \vec{V}_g = -\frac{2\Omega}{a} \cos \phi (2\Omega \sin \phi)^{-1} v_g
\]

\[
= -\frac{v_g \cos \phi}{a \sin \phi}
\]

\[
= -\frac{v_g \cot \phi}{a}
\]

\[
= -\frac{v_g \cot \phi}{R_E}
\]

The continuity equation

Lagrangian control volume: $\delta V = \delta x \delta y \delta z$
Hydrostatic equation:

\[ \frac{\delta p}{\delta z} = -\rho g \]

\[ \therefore \delta z = -\frac{1}{\rho g} \delta p \]

\[ \therefore \delta V = -\frac{1}{\rho g} \delta x \delta y \delta p \]

Mass, conserved following the motion:

\[ \delta M = \rho \delta V \]

\[ \therefore \delta M = -\frac{1}{g} \delta x \delta y \delta p \]

Thus,

\[ \frac{1}{\delta M} \frac{D}{Dt}(\delta M) = \frac{g}{\delta x \delta y \delta p} \frac{D}{Dt} \left( \frac{\delta x \delta y \delta p}{g} \right) = 0 \]

The last expression follows from the conservation of mass where \( \frac{D}{Dt}(\delta M) = 0 \implies \frac{1}{\delta M} \frac{D}{Dt}(\delta M) = \frac{0}{\delta M} \)

Therefore,

\[ \frac{g}{\delta x \delta y \delta p} \frac{D}{Dt} \left( \frac{\delta x \delta y \delta p}{g} \right) = 0 \] (Chain rule)

\[ \frac{1}{\delta x} \frac{D}{Dt} \delta x = \frac{1}{\delta y} \frac{D}{Dt} \delta y + \frac{1}{\delta p} \frac{D}{Dt} \delta p = 0 \]

\[ \frac{1}{\delta x} \delta \left( \frac{D x}{Dt} \right) + \frac{1}{\delta y} \delta \left( \frac{D y}{Dt} \right) + \frac{1}{\delta p} \delta \left( \frac{D p}{Dt} \right) = 0 \]

Taking limits as \( \delta x, \delta y, \delta p \to 0 \)

And \( \delta x, \delta y \) are evaluated at constant pressure

\[ \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right)_p + \frac{\partial \omega}{\partial p} = 0 \]

No density, no time derivative!

\[ \frac{\partial \omega}{\partial p} = -\nabla \cdot \nabla \]

Horizontal divergence: \( \nabla \cdot \nabla > 0 \implies \frac{\partial \omega}{\partial p} < 0 \), vertical squashing.
The thermodynamic energy equation

First law of Thermodynamics:

\[ c_p \frac{DT}{Dt} - \alpha \frac{Dp}{Dt} = J \]  \hspace{1cm} (2.42)

where \( \frac{Dp}{Dt} = \omega \) and \( J \) is the diabatic heating rate; the rate of heating per unit mass due to radiation, conduction, and latent heat release.

\[ \therefore c_p \left( \frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} + \omega \frac{\partial T}{\partial p} \right) - \alpha \omega = J \]

Equation of state: \( p\alpha = RT \)

\[ \therefore \left( \frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right) + \omega \frac{RT}{c_p} - \omega = J \]

\[ \therefore \left( \frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right) - \omega \left( \frac{RT}{c_p} - \frac{\partial T}{\partial p} \right) = J \]

\[ \frac{\partial T}{\partial t} + \nabla \cdot \nabla T - \omega \left( \frac{RT}{c_p} - \frac{\partial T}{\partial p} \right) = J \]

Static stability parameter for the isobaric system: \( S_p \equiv \frac{RT}{c_p} - \frac{\partial T}{\partial p} \)

\[ \therefore \frac{\partial T}{\partial t} + \nabla \cdot \nabla T - S_p \omega = J \]

It can be shown that \( S_p = \frac{\Gamma_d - \Gamma}{\rho g} \)

For observed lapse rate equal to the dry adiabatic lapse rate, \( S_p = 0 \)

\[ \therefore \frac{\partial T}{\partial t} + \nabla \cdot \nabla T = \frac{J}{c_p} \]

If the motion is adiabatic, \( J = 0 \)

\[ \therefore \frac{\partial T}{\partial t} + \nabla \cdot \nabla T = 0 \]

**Exercise 1:** A frontal zone moves over Tshwane overnight so that the local temperature falls at a rate of 1°C · h⁻¹. The wind is blowing from the South at 10 km · h⁻¹. The temperature is decreasing with latitude at a rate of 10°C per 100 km. Neglecting diabatic heating, and for the case of the observed lapse rate being equal to the dry adiabatic lapse rate, use the thermodynamic energy equation to describe the local rate of temperature change, and the advection of temperature over Tshwane.

**Solution:**

\[ \frac{\partial T}{\partial t} + \nabla \cdot \nabla T - S_p \omega = \frac{J}{c_p} \]
\[ \therefore \frac{\partial T}{\partial t} = -\nabla \cdot \nabla T \]

Left hand side: \[ \frac{\partial T}{\partial t} = -1^\circ C \cdot h^{-1} \]

Right hand side:

\[
-\nabla \cdot \nabla T = -(u \vec{i} + v \vec{j}) \cdot \left( \frac{\partial T}{\partial x} \vec{i} + \frac{\partial T}{\partial y} \vec{j} \right)
\]
\[= -u \frac{\partial T}{\partial x} - v \frac{\partial T}{\partial y} \]
\[= -v \frac{\partial T}{\partial y} \quad \text{(since } u = 0) \]
\[= -(10 \text{ km} \cdot h^{-1}) \left( \frac{-10^\circ C}{100 \text{ km}} \right) \quad (v > 0) \]
\[= 1^\circ C \cdot h^{-1} \]

In order for the left and right hand sides to be equal, the right-hand side must be reduced by \(2^\circ C \cdot h^{-1}\). Such a reduction may be caused by adiabatic cooling due to vertical advection.

\[ \therefore \text{Right hand side} = 1^\circ C \cdot h^{-1} - 2^\circ C \cdot h^{-1} \]
\[= -1^\circ C \cdot h^{-1} \]
\[= \text{Left hand side} \]

**Exercise 2:** Explain in words what this form of the thermodynamic energy equations represents:

\[ \frac{\partial T}{\partial t} + \nabla \cdot \nabla T = 0 \]

**Solution:** It represents the balance between the local rate of temperature change and the advection of temperature.
**Balanced flow**

Assumptions:

1. flows are steady state (i.e. time independent)
2. no vertical component of velocity

**Natural coordinates**

Defined by the orthogonal set of unit vectors \( \mathbf{\ell} \), \( \mathbf{\pi} \) and \( \mathbf{k} \)

\( \mathbf{\ell} \) : parallel to the horizontal velocity at each point
\( \mathbf{\pi} \) : normal to the horizontal velocity; positive to the left of the flow direction
\( \mathbf{k} \) : vertically upward

Horizontal velocity \( \mathbf{V} = V\mathbf{\ell} \); where \( V \) is the horizontal speed, non-negative scalar

\[
V \equiv \frac{D s}{D t}
\]

where \( s(x, y, t) \) is the distance along the curve of parcel.

Acceleration following the motion:

\[
\frac{D\mathbf{V}}{D t} = \frac{D(V\mathbf{\ell})}{D t} = \frac{D\mathbf{V}}{D t} \mathbf{\ell} + \frac{D\mathbf{\ell}}{D t} V
\]
According to the figure: $\delta s = |R| \delta \psi$ \quad \text{("s = r\theta")},

where $R$ is the radius of curvature following the parcel motion.

\[
\delta \psi = \frac{\delta s}{|R|} = \frac{\delta \ell}{|\ell|} \quad \text{(considered small triangle)}
\]
\[
\Rightarrow \frac{\delta s}{|R|} = |\delta \ell| \\
\frac{|\delta \ell|}{\delta s} = 1
\]

In the limit $\delta s \to 0$, $\delta \ell$ becomes parallel to $\pi$

\[
\Rightarrow \frac{D\ell}{Ds} = \frac{D\ell}{|\ell|} = \frac{\pi}{R} \quad \text{(because $\pi$ is a unit vector: $|\pi| = 1$)}
\]
\[
\frac{D\ell}{Dt} = \frac{D\ell}{Ds} \frac{Ds}{Dt} = \frac{\pi}{R} V \quad \left( V \equiv \frac{Ds}{Dt} \right)
\]
\[
\Rightarrow \frac{D\overline{V}}{Dt} = \overline{t} \frac{DV}{Dt} + V \left( \frac{\pi}{R} V \right)
\]
\[
\frac{D\overline{V}}{Dt} = \overline{t} \frac{DV}{Dt} + \frac{\pi V^2}{R}
\]

(3.8)

where:

- $\frac{D\overline{V}}{Dt}$ is the acceleration following the motion.

- $\overline{t} \frac{DV}{Dt}$ is the rate of change of speed of the air parcel.

- $\frac{\pi V^2}{R}$ is the centripetal acceleration due to curvature of trajectory.
Acceleration due to Coriolis force:

\[= - f \bar{k} \times \bar{V} \]
\[= - f \bar{k} \times \bar{V} \bar{t} \]
\[= - f \bar{V} \bar{n} \]

Horizontal pressure gradient = \(-\nabla \Phi\)

In natural coordinate system: 

\[= - \nabla \Phi = - \left( \bar{t} \frac{\partial \Phi}{\partial s} + \bar{n} \frac{\partial \Phi}{\partial n} \right) \]

Since 

\[
\frac{DV}{Dt} = - f \bar{k} \times \bar{V} - \nabla \Phi = - f \bar{V} \bar{n} - \left( \bar{t} \frac{\partial \Phi}{\partial s} + \bar{n} \frac{\partial \Phi}{\partial n} \right) 
\]

And 

\[
\frac{DV}{Dt} = \bar{t} \frac{DV}{Dt} + \bar{n} \frac{V^2}{R} 
\]

\[
\frac{DV}{Dt} = - \frac{\partial \Phi}{\partial s}, \quad \text{and} \quad \frac{V^2}{R} = - f \bar{V} - \frac{\partial \Phi}{\partial n} \implies \frac{V^2}{R} + f \bar{V} = - \frac{\partial \Phi}{\partial n} 
\]

\[
\frac{DV}{Dt} = - \frac{\partial \Phi}{\partial s} : \text{force balance parallel to the direction of flow.} 
\]

\[
\frac{V^2}{R} + f \bar{V} = - \frac{\partial \Phi}{\partial n} : \text{force balance normal to the direction of flow.} 
\]

For motion parallel to geopotential height then \(\Phi\) remains unchanged:

\[
\frac{\partial \Phi}{\partial s} = 0 
\]
\[
\therefore \frac{DV}{Dt} = 0 
\]

\[\implies \text{Speed is constant following the motion} \]
If the geopotential gradient normal to the direction of motion is constant along a trajectory

\[
\frac{\partial \Phi}{\partial n} = 0
\]

\[
\therefore \frac{V^2}{R} + fV = 0
\]

\[
\therefore R = \frac{-V^2}{fV} = \frac{-V}{f}
\]

\[\Rightarrow \text{radius of curvature, } R, \text{ is constant.}\]

**Geostrophic flow**

Geostrophic motion: flow in a straight line \((R \to \pm \infty)\) parallel to height contours.

For \(R \to \pm \infty, \frac{V^2}{R} \to 0\)

In geostrophic motion the horizontal components of the Coriolis force and pressure gradient force are in **exact balance**, thus \(V = V_g\)

\[
\therefore 0 + fV = fV_g = -\frac{\partial \Phi}{\partial n}
\]

(3.11)

**The balance**

The actual wind can be in exact geostrophic motion only if the height contours are parallel to latitude circles.

Although the geostrophic wind is generally a good approximation to the actual wind in extra-tropical synoptic-scale disturbances, in some special cases this is not true!

**Inertial flow**

If the geopotential field is uniform on an isobaric surface so that the horizontal pressure gradient vanishes \(\left(\frac{\partial \Phi}{\partial n} = 0\right)\):

\[
\frac{V^2}{R} + fV = 0
\]

(3.12)
(3.12): Coriolis force and centrifugal force are balanced.

\[ R = -\frac{V}{f} \]

**NOTE:**

1) In the atmosphere motions are nearly always generated and maintained by pressure gradient forces.
2) The condition of uniform pressure required for pure inertial flow rarely exist.

**Balanced flow**

Consider the natural coordinate system where the unit vector \( \overline{n} \) is normal to the horizontal velocity and is positive to the left of the flow direction. This configuration applies to both hemispheres.

\[ \overline{n} \]

\( R > 0 \) for cyclonic flow
\( R < 0 \) for anticyclonic flow

\( R > 0 \) when the centre of curvature is in the positive \( \overline{n} \) direction.

** Regarding \( \frac{\partial \Phi}{\partial n} \):**

For the NH:

For LOW pressure system

\[ \delta \Phi < 0 \quad (\text{geopotential decreases towards centre}) \]
\[ \delta n > 0 \quad (\overline{n} \text{ pointing towards centre of low}) \]

\[ \therefore \frac{\partial \Phi}{\partial n} < 0 \]
For HIGH pressure system

\[ \delta \Phi > 0 \quad \text{ (geopotential increases towards centre) } \]
\[ \delta n < 0 \quad \text{ (n pointing towards centre of low) } \]
\[ \therefore \frac{\partial \Phi}{\partial n} < 0 \]

For the SH:

For LOW pressure system \( \delta \Phi < 0, \delta n < 0 \) therefore \( \frac{\partial \Phi}{\partial n} > 0 \)

For HIGH pressure system \( \delta \Phi > 0, \delta n > 0 \) therefore \( \frac{\partial \Phi}{\partial n} > 0 \)

**Cyclostrophic flow**

If the horizontal scale of an atmospheric disturbance is small enough, the Coriolis force may be neglected when compared with the centrifugal force and the pressure gradient force:

Centrifugal force \( \frac{V^2}{R} \gg fV \)

Pressure gradient force \( \frac{\partial \Phi}{\partial n} \gg fV \)

From Eq. (3.10):

\[
\frac{V^2}{R} = -\frac{\partial \Phi}{\partial n}
\]

\[ V = \left(-R\frac{\partial \Phi}{\partial n}\right)^{1/2}, \quad \text{the cyclostrophic wind speed.} \]

**Case 1:** \( R > 0 \) and \( \frac{\partial \Phi}{\partial n} > 0 \)

\[ R\frac{\partial \Phi}{\partial n} > 0 \]
\[ \therefore -R\frac{\partial \Phi}{\partial n} < 0 \]
\[ \implies \text{Negative root, V physically impossible} \]

**Case 2:** \( R < 0 \) and \( \frac{\partial \Phi}{\partial n} > 0 \)

\[ R\frac{\partial \Phi}{\partial n} < 0 \]
\[ \therefore -R\frac{\partial \Phi}{\partial n} > 0 \]
\[ \implies \text{Positive root, V physically possible} \]
**Case 3:** $R > 0$ and $\frac{\partial \Phi}{\partial n} < 0$

\[ R \frac{\partial \Phi}{\partial n} < 0 \]

\[ \therefore -R \frac{\partial \Phi}{\partial n} > 0 \]

$\implies$ Negative root, $V$ physically possible

**Case 4:** $R < 0$ and $\frac{\partial \Phi}{\partial n} < 0$

\[ R \frac{\partial \Phi}{\partial n} > 0 \]

\[ \therefore -R \frac{\partial \Phi}{\partial n} < 0 \]

$\implies$ Negative root, $V$ physically impossible

The mathematically positive roots of the speed of the cyclostrophic wind correspond to only two physically possible solutions:

$R < 0$ and $\frac{\partial \Phi}{\partial n} > 0$ (Case 2)

and

$R > 0$ and $\frac{\partial \Phi}{\partial n} < 0$ (Case 3)

Consider the figures on the next page. Since the Coriolis force is not a factor, around lows, cyclostrophic winds can turn either clockwise or counterclockwise. As discussed in the balanced flow section, $\pi$ is positive to the left of the flow direction, $R > 0$ when curvature centre is in $\pi$ direction.

Therefore,

NH: Cyclonic flow $R > 0$ and anticyclonic flow $R < 0$

SH: Cyclonic flow $R < 0$ and anticyclonic flow $R > 0$

**Regarding $\frac{\partial \Phi}{\partial n}$:**

Since we are dealing here with (intense) low pressure systems $\delta \Phi < 0$ for cyclonic and anticyclonic flow, and for both hemispheres.

NH: Cyclonic flow $\delta n > 0$ therefore $\frac{\partial \Phi}{\partial n} < 0$

SH: Cyclonic flow $\delta n < 0$ therefore $\frac{\partial \Phi}{\partial n} > 0$

NH: Anticyclonic flow $\delta n < 0$ therefore $\frac{\partial \Phi}{\partial n} > 0$

SH: Anticyclonic flow $\delta n > 0$ therefore $\frac{\partial \Phi}{\partial n} < 0$

Exercise: By means of drawing circular symmetric motion figures, explain why there can be no cyclostrophic balance around a small high pressure centre.

Solution:

Regular LOW

Regular HIGH
For cyclostrophic flow, the Coriolis force becomes negligible compared with other two forces. For a LOW, there can still be balance. In this case between Ce and Pgf. However, for a HIGH, Ce and Pgf point in the same direction. So no balance is possible here.

**The gradient wind approximation**

**Gradient Flow**: Horizontal frictionless flows that is parallel to the height contours so that the tangential acceleration vanishes, i.e. \( \frac{DV}{Dt} = 0 \).

**Gradient Flow** is a 3-way balance among:

1) The Coriolis force
2) The centrifugal force
3) The horizontal pressure gradient force

A **gradient wind** is just the wind component parallel to the height contour that satisfies:

\[
\frac{V^2}{R} + fV = - \frac{\partial \Phi}{\partial n}
\]

the gradient wind equation (3.10)

For a quadratic equation \( ax^2 + bx + c = 0 \), solving the equation for \( x \)

\[
x = \frac{-b \pm (b^2 - 4ac)^{1/2}}{2a}
\]

Therefore, solving for \( V \) in Eq. (3.10), \( a = \frac{1}{R}, b = f, c = \frac{\partial \Phi}{\partial n} \)

\[
V = \frac{-f \pm \left( f^2 - 4 \frac{1}{R} \frac{\partial \Phi}{\partial n} \right)^{1/2}}{2 \frac{1}{R}}
\]

\[
= \frac{-f R}{2} \pm \frac{R}{2} \left( f^2 - 4 \frac{\partial \Phi}{R \partial n} \right)^{1/2}
\]

\[
= \frac{-f R}{2} \pm \left( \frac{R}{2} \right)^2 \left( f^2 - 4 \frac{\partial \Phi}{R \partial n} \right)^{1/2}
\]

For geostrophic flow

\[
fV_g = - \frac{\partial \Phi}{\partial n}
\]

\[
\therefore \frac{\partial \Phi}{\partial n} = -fV_g
\]
\[ V = \frac{-fR}{2} \pm \left( \frac{f^2R^2}{4} + fRV_g \right)^{\frac{1}{2}} \] (3.15)

Determining the **mathematically possible roots** of (3.15)

\[ V = \frac{-fR}{2} \pm \left( \frac{f^2R^2}{4} + fRV_g \right)^{\frac{1}{2}} \]

By the geostrophic approximation \( V_g = -\frac{1}{f} \frac{\partial \Phi}{\partial n} \) i.e. the **pressure gradient**

\[ V = -\frac{fR}{2} \pm \left( \frac{f^2R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{\frac{1}{2}} \] (A)

**Objective**: Determine the cases for which the solution of (A) is both positive and real

**The gradient wind approximation: SOUTHERN HEMISPHERE** \((f < 0)\)

**Case 1**: For \( R > 0 \) and \( \frac{\partial \Phi}{\partial n} > 0 \)

\[ fR < 0, \quad -\frac{fR}{2} > 0 \]
\[ R \frac{\partial \Phi}{\partial n} > 0, \quad -R \frac{\partial \Phi}{\partial n} < 0 \]

Since \( V \) has to be real, \( \frac{f^2R^2}{4} - R \frac{\partial \Phi}{\partial n} > 0 \)

\[ V = -\frac{fR}{2} \pm \left( \frac{f^2R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{\frac{1}{2}} \]

For **positive** root:

\[ V = \text{Positive value} \left( -\frac{fR}{2} \right) + \text{positive}(+\sqrt{\cdot}) \]
\[ \therefore V > 0, \text{ and therefore physically possible.} \]

For **negative** root: Consider \( \frac{f^2R^2}{4} > 0 \)

\[ \therefore \frac{f^2R^2}{4} > \frac{f^2R^2}{4} - R \frac{\partial \Phi}{\partial n} \quad \text{(since} \ R \frac{\partial \Phi}{\partial n} < 0 \text{)} \]
\[ \therefore \pm \left( \frac{f^2R^2}{4} \right)^{\frac{1}{2}} > \pm \left( \frac{f^2R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{\frac{1}{2}} \]

20
But we are considering negative roots:

\[- \left( \frac{f^2 R^2}{4} \right)^{1/2} < - \left( \frac{f^2 R^2}{4} - \frac{R \partial \Phi}{\partial n} \right)^{1/2} \]

\[\therefore - \frac{f R}{2} - \left( \frac{f^2 R^2}{4} \right)^{1/2} < - \frac{f R}{2} - \left( \frac{f^2 R^2}{4} - \frac{R \partial \Phi}{\partial n} \right)^{1/2} = V \]

\[\therefore V > - \frac{f R}{2} - \left( \frac{f^2 R^2}{4} \right)^{1/2} = - \frac{f R}{2} - \left| \frac{f R}{2} \right| = - \frac{f R}{2} - \left( - \frac{f R}{2} \right) \]

\[\therefore V > 0, \text{ and therefore physically possible.} \]

\[
\begin{array}{|c|}
\hline
\text{*} \\
\hline
|x| = x \quad \text{for} \quad x > 0 \\
|x| = -x \quad \text{for} \quad x < 0 \\
\hline
\end{array}
\]

**Case 2:** For \( R < 0 \) and \( \frac{\partial \Phi}{\partial n} > 0 \)

\[f R > 0, \quad - \frac{f R}{2} < 0 \]

\[R \frac{\partial \Phi}{\partial n} < 0, \quad -R \frac{\partial \Phi}{\partial n} > 0 \]

For real \( V, \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} > 0 \)

For **negative** root:

\[V = - \frac{f R}{2} - \left( \frac{f^2 R^2}{4} - \frac{R \partial \Phi}{\partial n} \right)^{1/2} \]

\[= \text{negative value} - \text{positive value} \]

\[\therefore V < 0, \text{ and therefore physically impossible.} \]

For **positive** root: \( \frac{f^2 R^2}{4} > 0 \)

\[\frac{f^2 R^2}{4} < \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \quad \text{(since} \quad -R \frac{\partial \Phi}{\partial n} > 0) \]

\[\therefore \pm \left( \frac{f^2 R^2}{4} \right)^{1/2} < \pm \left( \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{1/2} \]
But we are considering positive roots:

\[+ \left( \frac{f^2 R^2}{4} \right)^{1/2} < + \left( \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{1/2}\]

\[\therefore \quad -\frac{fR}{2} + \left( \frac{f^2 R^2}{4} \right)^{1/2} < -\frac{fR}{2} + \left( \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{1/2} = V\]

\[\therefore \quad V > -\frac{fR}{2} - \left( \frac{f^2 R^2}{4} \right)^{1/2} = -\frac{fR}{2} + \left| \frac{fR}{2} \right| = -\frac{fR}{2} + \frac{fR}{2}\]

\[\therefore \quad V > 0, \text{ and therefore physically possible.}\]

**Case 3:** For \(R > 0\) and \(\frac{\partial \Phi}{\partial n} < 0\)

\[fR < 0, \quad -\frac{fR}{2} > 0\]

\[R \frac{\partial \Phi}{\partial n} < 0, \quad -R \frac{\partial \Phi}{\partial n} > 0\]

Since \(V\) has to be real, \(\frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} > 0\)

For **positive** root:

\[V = \text{positive value} \left( -\frac{fR}{2} \right) + \text{positive value}(+\sqrt{\cdot})\]

\[\therefore \quad V > 0, \text{ and therefore physically possible.}\]

For **negative** root: \(\frac{f^2 R^2}{4} > 0\)

\[\therefore \quad \frac{f^2 R^2}{4} < \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \quad \left( \text{since } -R \frac{\partial \Phi}{\partial n} > 0 \right)\]

\[\therefore \quad \pm \left( \frac{f^2 R^2}{4} \right)^{1/2} < \pm \left( \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{1/2}\]

But we are considering negative roots:

\[- \left( \frac{f^2 R^2}{4} \right)^{1/2} > - \left( \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{1/2}\]

\[\therefore \quad -\frac{fR}{2} - \left( \frac{f^2 R^2}{4} \right)^{1/2} > -\frac{fR}{2} - \left( \frac{f^2 R^2}{4} - R \frac{\partial \Phi}{\partial n} \right)^{1/2} = V\]

\[\therefore \quad V < -\frac{fR}{2} - \left( \frac{f^2 R^2}{4} \right)^{1/2} = -\frac{fR}{2} - \left| \frac{fR}{2} \right| = -\frac{fR}{2} - \left( -\frac{fR}{2} \right) \quad \left( \text{since } \frac{fR}{2} < 0 \right)\]

\[\therefore \quad V < 0, \text{ and therefore physically impossible.}\]
**Case 4:** For $R < 0$ and $\frac{\partial \Phi}{\partial n} < 0$

\[ fR > 0, \quad -\frac{fR}{2} < 0 \]
\[ R\frac{\partial \Phi}{\partial n} > 0, \quad -R\frac{\partial \Phi}{\partial n} < 0 \]

For real $V$, $\frac{f^2 R^2}{4} - R\frac{\partial \Phi}{\partial n} > 0$

For **negative** root:

\[ V = -\frac{fR}{2} - \left( \frac{f^2 R^2}{4} - R\frac{\partial \Phi}{\partial n} \right)^{1/2} \]

= negative value – positive value

\[ \therefore V < 0, \text{ and therefore physically impossible.} \]

For **positive** root: $\frac{f^2 R^2}{4} > 0$

\[ \frac{f^2 R^2}{4} > \frac{f^2 R^2}{4} - R\frac{\partial \Phi}{\partial n} \quad \left( \text{since} \ -R\frac{\partial \Phi}{\partial n} < 0 \right) \]

\[ \therefore \pm \left( \frac{f^2 R^2}{4} \right)^{1/2} > \pm \left( \frac{f^2 R^2}{4} - R\frac{\partial \Phi}{\partial n} \right)^{1/2} \]

But we are considering positive roots:

\[ + \left( \frac{f^2 R^2}{4} \right)^{1/2} > + \left( \frac{f^2 R^2}{4} - R\frac{\partial \Phi}{\partial n} \right)^{1/2} \]

\[ \therefore \ -\frac{fR}{2} + \left( \frac{f^2 R^2}{4} \right)^{1/2} > -\frac{fR}{2} + \left( \frac{f^2 R^2}{4} - R\frac{\partial \Phi}{\partial n} \right)^{1/2} = V \]

\[ \therefore V < -\frac{fR}{2} - \left( \frac{f^2 R^2}{4} \right)^{1/2} = -\frac{fR}{2} + \left| \frac{fR}{2} \right| = -\frac{fR}{2} + \frac{fR}{2} \]

\[ \therefore V < 0, \text{ and therefore physically impossible.} \]

The following table is a summary of the four cases

**Gradient wind classification in the Southern Hemisphere**
\[
\frac{\partial \Phi}{\partial n} (+/-) \quad R > 0 \text{ (anticyclonic)} \quad R < 0 \text{ (cyclonic)}
\]

For **cyclonic** flow \((R < 0)\) the only physically possible configuration is:

\[
R < 0 \text{ and } \frac{\partial \Phi}{\partial n} > 0 \quad \text{(similar to result in the cyclostrophic wind classification section)}
\]

\[
\frac{\partial \Phi}{\partial n} > 0 \text{ makes sense since } \delta \Phi < 0 \text{ and } \delta n < 0. \text{ Also consider the geostrophic wind equation}
\]

\[
V_g = -\frac{1}{f} \frac{\partial \Phi}{\partial n} \quad \text{(3.11)}
\]

\[
\therefore V_g = -\frac{1}{f} (\text{pos}) > 0
\]

So, for \( \frac{\partial \Phi}{\partial n} > 0 \): \( V_g = -\frac{1}{(\text{neg})} \text{ (pos) } > 0 \) as was found for cyclonic flow.

However, for \( \frac{\partial \Phi}{\partial n} < 0 \): \( V_g = -\frac{1}{(\text{neg})} \text{ (neg) } < 0 \)

According to equation (3.17) of Holton 4, \( V_g = V \left( 1 + \frac{V}{fR} \right) \). Since \( V \) is required to be positive, a negative \( V_g \) is not a useful approximation to actual speed. Therefore, anticyclonic flow is more likely to have the following configuration: \( R > 0 \) and \( \frac{\partial \Phi}{\partial n} > 0 \).

To summarise, for cyclonic flow of the gradient wind, \( R < 0 \) and \( \frac{\partial \Phi}{\partial n} > 0 \), while for anticyclonic flow, \( R > 0 \) and \( \frac{\partial \Phi}{\partial n} > 0 \). This result is similar to what was found in the balanced flow section.

\[
\frac{V^2}{R} + fV = -\frac{\partial \Phi}{\partial n} \quad \text{(3.10)}
\]

The geostrophic wind is defined by

\[
fV_g = -\frac{\partial \Phi}{\partial n} \quad \text{(3.11)}
\]
\[
\begin{align*}
\therefore \frac{V^2}{R} + fV &= fV_g \\
\frac{1}{fV} \left( \frac{V^2}{R} + fV \right) &= \frac{1}{fV} (fV_g) \\
\frac{V}{fR} + 1 &= \frac{V_g}{V}, \text{the ratio of the geostrophic wind to the gradient wind.}
\end{align*}
\]

From the balanced flow section:

Northern Hemisphere \((f > 0)\):

\[
\begin{align*}
R > 0 \text{ for cyclonic flow} \\
R < 0 \text{ for anticyclonic flow}
\end{align*}
\]

\[
\therefore Rf > 0 \text{ for cyclonic flow} \\
Rf < 0 \text{ for anticyclonic flow}
\]

Southern Hemisphere \((f < 0)\):

\[
\begin{align*}
R < 0 \text{ for cyclonic flow} \\
R > 0 \text{ for anticyclonic flow}
\end{align*}
\]

\[
\therefore Rf > 0 \text{ for cyclonic flow} \\
Rf < 0 \text{ for anticyclonic flow}
\]

Typical values for \(V, f\) and \(R\): \(5 \text{ m} \cdot \text{s}^{-1}, 10^{-4} \text{ s}^{-1}\) and \(500 \text{ km}\).

\[
\therefore \frac{V}{fR} = \frac{5 \text{ m} \cdot \text{s}^{-1}}{10^{-4} \text{ s}^{-1} 500000 \text{ m}} = 0.1
\]

For cyclonic flow (both hemispheres):

\[
\frac{V_g}{V} = 1 + 0.1 = 1.1
\]

\[
\therefore V_g = 1.1 \times V
\]

\[
\implies V_g > V
\]

For anticyclonic flow (both hemispheres):

\[
\frac{V_g}{V} = 1 - 0.1 = 0.9
\]

\[
\therefore V_g = 0.9 \times V
\]

\[
\implies V_g < V
\]
Therefore, the geostrophic wind is an overestimate of the balanced wind in a region of cyclonic curvature, and an underestimate in a region of anticyclonic curvature.

**Exercise 1:** Consider an anticyclone and the case of positive pressure gradient forces. At a radius of 100 km and associated geostrophic wind speed of 2.4 m s\(^{-1}\), calculate the gradient wind speeds. Is the ratio between the given geostrophic wind and the calculated gradient winds in agreement with your result found above? Next, redo the gradient wind calculation, but this time double the geostrophic wind speed and interpret this result. The Coriolis parameter is \(-10^{-4}\) s\(^{-1}\).

**Solution:**

For anticyclone: \(R > 0\) and (given) \(\frac{\partial \Phi}{\partial n} > 0\)

\[
R = 100\,000\,\text{m} \\
V_g = 2.4\,\text{m s}^{-1} \\
f = -10^{-4}\,\text{s}^{-1}
\]

\[
V = -\frac{fR}{2} \pm \left( \frac{f^2R^2}{4} + fRV_g \right)^{\frac{1}{2}}
\]

\[
= -\frac{(-10^{-4})(100\,000)}{2} \pm \left( \frac{(-10^{-4})^2(100\,000)^2}{4} + (-10^{-4})(100\,000)(2.4) \right)^{\frac{1}{2}}
\]

\[
= 5 \pm (25 - 24)^{\frac{1}{2}}
\]

\[
= 5 \pm 1\,\text{m s}^{-1}
\]

For positive root: \(V = 6\,\text{m s}^{-1}\)

For negative root: \(V = 4\,\text{m s}^{-1}\)

For anticyclonic flow, it has been demonstrated that:

\[
V_g < V
\]

Since both \(V\) solutions are greater than 2.4 m s\(^{-1}\), the given geostrophic wind speed. Therefore, the ratio between the geostrophic wind and the gradient wind is in agreement with the result.

For double geostrophic wind, \(V_g = 4.8\,\text{m s}^{-1}\)

\[
V = 5 \pm (25 - 48)^{\frac{1}{2}}
\]

\[
= 5 \pm (\text{negative value})^{\frac{1}{2}}
\]

Therefore, 4.8 m s\(^{-1}\) as a geostrophic wind is unrealistically high since this leads to an unphysical solution for \(V\).

**Exercise 2:** When the two terms under the square root of the solved quadratic equation (3.10) are perfectly balanced (their sum equals zero), determine the ratio of the anticyclonic gradient wind speed to the geostrophic wind speed for the same pressure gradient.
Solution:

\[ V = -\frac{f R}{2} \pm \left( \frac{f^2 R^2}{4} + f R V_g \right)^{\frac{1}{2}} \]

Given: \[ \frac{f^2 R^2}{4} + f R V_g = 0 \implies V = -\frac{f R}{2} \]

\[ \therefore \frac{f R}{4} + V_g = 0 \]

\[ \therefore -\frac{2V}{4} + V_g = 0 \]

\[ \therefore V = 2V_g \]

\[ \therefore \frac{V}{V_g} = 2 \]

**Exercise 3:** Show that as the pressure gradient approaches zero the gradient wind reduces to the geostrophic wind for a normal anticyclone [Hint: make use of this approximation: when variable \( x \) approaches zero, the square root of \( 1 + x \) is equal to \( 1 + x/2 \)].

**Solution:** Since the pressure gradient approaches zero, so does \( V_g \) because \( V_g = -\frac{1}{f} \frac{\partial \Phi}{\partial n} \).

The following approximation has been given: when \( x \to 0 \), \( (1 + x)^{1/2} = 1 + \frac{x}{2} \).

We therefore consider the square root term of the gradient wind equation:

\[ \pm \left( \frac{f^2 R^2}{4} + f R V_g \right)^{\frac{1}{2}} = \pm \left[ \frac{f^2 R^2}{4} \left( 1 + \frac{4V_g}{f R} \right) \right]^{\frac{1}{2}} \]

\[ = \pm \frac{f R}{2} \left( 1 + \frac{4V_g}{f R} \right)^{\frac{1}{2}} \]

\[ = \pm \frac{f R}{2} \left( 1 + \frac{1}{2} \cdot \frac{4V_g}{f R} \right)^{\frac{1}{2}} \]

\[ \therefore V = -\frac{f R}{2} \pm \frac{f R}{2} \left( 1 + \frac{2V_g}{f R} \right) \]

For this case, we are only interested in the positive root.

\[ \therefore V = -\frac{f R}{2} + \frac{f R}{2} + V_g \]

\[ \therefore V = V_g \]

**Additional information**

This section aims to add more information relating to the Coriolis parameter and \( \beta \).

The figure below shows the plot of the Coriolis parameter with latitude. The Coriolis parameter varies from \( \pm 1.4584 \times 10^{-4} \) \( s^{-1} \) at the poles to 0 at the equator. Note how, in the mid-latitudes, the magnitude of \( f \) (i.e., \( |f| \)) is close to 1 \( (\times 10^{-4} \) \( s^{-1} \)). Therefore, the approximation of \( f \) in our work is sufficient.
The variation of the Coriolis parameter with latitude ($\beta$) is shown below. $\beta$ remains fairly constant and small over the equator and tropics. This explains why there are no Rossby waves over this domain since they owe their existence to the variation of the Coriolis parameter with latitude, the so-called $\beta$-effect.
The thermal wind

Isobaric coordinate form of the geostrophic relationship:

\[ f \overline{V_g} = \overline{k} \times \nabla \Phi \Phi : \text{geopotential} \]

\[ \Rightarrow \text{geostrophic wind } \propto \text{geopotential gradient.} \]

\[ \Rightarrow \text{geostrophic wind directed along the positive } y\text{-axis that increases in magnitude with height requires that the slope of the isobaric surfaces with respect to the } x\text{-axis must increase with height.} \]

Hypsometric equation \( \Phi(z_2) - \Phi(z_1) = g(z_2 - z_1) = R \int_{p_1}^{p_2} T d \ln p \)

For thickness \( \delta z \) corresponding to a pressure interval \( \delta p \)

\[ \delta z \approx -\frac{1}{g} RT \delta \ln p \]
thickness of the layer between isobaric surfaces \( \propto \) temperature of the layer:

\[
T(\delta z_1) < T(\delta z_2)
\]

increase of height of a positive \( x \)-directed pressure gradient is associated with a positive \( x \)-directed temperature gradient

the air in a vertical column at \( x_2 \), because it is warmer (less dense), must occupy a greater depth for a given pressure drop than the air at \( x_1 \)

From \( \nabla_g = \frac{1}{f} \kappa \times \nabla_p \Phi \), in isobaric coordinates:

\[
v_g = \frac{1}{f} \frac{\partial \Phi}{\partial x} \quad \text{and} \quad u_g = -\frac{1}{f} \frac{\partial \Phi}{\partial y}
\]

Equation of state for an ideal gas: \( p\alpha = RT \) or \( p = \rho RT \)

where \( \alpha = \rho^{-1} \)

Geopotential: \( \delta \Phi = g \delta z \implies \delta z = \frac{1}{g} \delta \Phi \)

Hydrostatic equation: \( \frac{\delta p}{\delta z} = -\rho g \implies \frac{\delta z}{\delta p} = -\frac{1}{\rho g} \)

\[
\therefore \frac{1}{g} \frac{\delta \Phi}{\delta p} = -\alpha \frac{g}{g} = -\alpha
\]

\[
\lim_{\delta p \to 0} \frac{\delta \Phi}{\delta p} = -\alpha = -\frac{RT}{p}
\]

\[
\therefore T = \frac{p}{R} \frac{\partial \Phi}{\partial p}
\]

Differentiate geostrophic wind components with respect to pressure:

\[
\frac{\partial v_g}{\partial p} = \frac{1}{f} \frac{\partial}{\partial x} \left( \frac{\partial \Phi}{\partial p} \right) = \frac{1}{f} \frac{\partial}{\partial x} \left( -\frac{RT}{p} \right)
\]

\[
\therefore p \frac{\partial v_g}{\partial p} = -\frac{R}{f} \left( \frac{\partial T}{\partial x} \right)_p
\]

\[
\therefore \frac{\partial v_g}{\partial \ln p} = -\frac{R}{f} \left( \frac{\partial T}{\partial x} \right)_p
\]

\[
\frac{\partial u_g}{\partial p} = \frac{1}{f} \frac{\partial}{\partial y} \left( \frac{\partial \Phi}{\partial p} \right) = \frac{1}{f} \frac{\partial}{\partial y} \left( -\frac{RT}{p} \right)
\]

\[
\therefore \frac{\partial u_g}{\partial \ln p} = \frac{R}{f} \left( \frac{\partial T}{\partial y} \right)_p
\]
As a vector:
\[
\frac{\partial \mathbf{V}_g}{\partial \ln p} = -\frac{R}{f} \mathbf{k} \times \nabla_p T
\]
the thermal wind equation (3.30)

\[
\nabla_T = -\frac{R}{f} \int_{p_0}^{p_1} \mathbf{k} \times \nabla_p T d \ln p
\]
(3.31)

\(\langle T \rangle\) is the mean temperature in the layer between \(p_0\) and \(p_1\).

\[
u_T = -\frac{R}{f} \left( \frac{\partial \langle T \rangle}{\partial y} \right)_p \int_{p_0}^{p_1} d \ln p
\]
(3.32)

\[
v_T = \frac{R}{f} \left( \frac{\partial \langle T \rangle}{\partial x} \right)_p \int_{p_0}^{p_1} d \ln p
\]
(3.32)

**Thermal wind** is the vector difference between geostrophic winds at two levels:

\[
\nabla_T \equiv \mathbf{V}_g(p_1) - \mathbf{V}_g(p_0) \quad (p_1 < p_0)
\]

also \(u_T = u_{g_1} - u_{g_0} = -\frac{1}{f} \frac{\partial}{\partial y}(\Phi_1) - \left(-\frac{1}{f} \frac{\partial}{\partial y}(\Phi_0)\right)\)

\[
= -\frac{1}{f} \frac{\partial}{\partial y}(\Phi_1 - \Phi_0)
\]
(3.33)

\(v_T = v_{g_1} - v_{g_0} = \frac{1}{f} \frac{\partial}{\partial x}(\Phi_1) - \frac{1}{f} \frac{\partial}{\partial x}(\Phi_0)\)

\[
= \frac{1}{f} \frac{\partial}{\partial x}(\Phi_1 - \Phi_0)
\]
(3.33)

\[
\Rightarrow -\frac{R}{f} \left( \frac{\partial \langle T \rangle}{\partial y} \right)_p \ln \left( \frac{p_0}{p_1} \right) = -\frac{1}{f} \frac{\partial}{\partial y}(\Phi_1 - \Phi_0)
\]

\[
\Rightarrow R \ln \left( \frac{p_0}{p_1} \right) \int \frac{\partial \langle T \rangle}{\partial y} dy = \int \frac{\partial}{\partial y}(\Phi_1 - \Phi_0) dy
\]

\[
\Rightarrow \Phi_1 - \Phi_0 = R \langle T \rangle \ln \left( \frac{p_0}{p_1} \right)
\]
(3.34)

Per definition: \(\Phi_1 - \Phi_0 \equiv Z_T g\), where \(Z_T\) is the **thickness**.
Also

\[
\frac{R}{f} \left( \frac{\partial \langle T \rangle}{\partial x} \right)_p \ln \left( \frac{p_0}{p_1} \right) = \frac{1}{f} \frac{\partial}{\partial x} (\Phi_1 - \Phi_0)
\]

\[
R \ln \left( \frac{p_0}{p_1} \right) \int \frac{\partial \langle T \rangle}{\partial x} \, dx = \int \frac{\partial}{\partial x} (\Phi_1 - \Phi_0) \, dx
\]

\[\implies \Phi_1 - \Phi_0 = R \langle T \rangle \ln \left( \frac{p_0}{p_1} \right) \quad (3.34)\]

The thickness is therefore proportional to the mean temperature in the layer.

\[\implies \text{lines of equal thickness are equivalent to the isotherms of mean temperature in the layer.}\]

(3.35):

\[
\nabla_T = \frac{1}{f} E \times \nabla (\Phi_1 - \Phi_0) = \frac{g}{f} E \times \nabla Z_T = \frac{R}{f} E \times \nabla \langle T \rangle \ln \left( \frac{p_0}{p_1} \right)
\]

\[\text{From (3.33)} \quad \text{From (3.33),(3.34)} \quad \text{From (3.32)}\]

**Exercise 1:** The mean temperature in the layer between 750 and 500 hPa **decreases eastward** by 2°C per 100 km. If the 700 hPa geostrophic wind is from the southeast at 20 m s\(^{-1}\), what is the geostrophic wind speed at 500 hPa? Let \(f = -10^{-4} \text{s}^{-1}\) [Hint: remember Pythagoras when calculating the geostrophic wind components].

**Solution:** The mean temperature decreases eastward, so there is no north–south component: \(\frac{\partial \langle T \rangle}{\partial y} = 0\) and \(\frac{\partial \langle T \rangle}{\partial x} < 0\)

\[\therefore \, u_T = 0\]

\[v_T = \frac{R}{f} \left( \frac{\partial \langle T \rangle}{\partial x} \right)_p \ln \left( \frac{p_0}{p_1} \right) \]

where \(R\) is the gas constant for dry air:

\[
R = 287 \, \text{J K}^{-1} \text{kg}^{-1}
\]

\[= 287 \, \text{N m K}^{-1} \text{kg}^{-1}\]

\[= 287 \, \text{kg m s}^{-2} \text{m K}^{-1} \text{kg}^{-1}\]

\[= 287 \, \text{m}^2 \text{s}^{-2} \text{K}^{-1}\]

\[\therefore \, v_T = \frac{287 \, \text{m}^2 \text{s}^{-2} \text{K}^{-1}}{-10^{-4} \text{s}^{-1}} \left( -\frac{2 \, \text{K}}{100 \, 000 \text{ m}} \right) \ln \left( \frac{750}{500} \right)\]

\[= 23.27 \, \text{m s}^{-1}\]

At 750 hPa:
\[ c^2 = a^2 + b^2 = 2a^2 \implies a = \left( \frac{20^2}{2} \right)^{1/2} = b = 14.14 \text{ m s}^{-1} \]

\[ u_T = u_g(500) - u_g(750) = -14.14 \text{ m s}^{-1} \]

\[ v_T = v_g(500) - v_g(750) = 37.41 \text{ m s}^{-1} \]

\[ \therefore \bar{V}_g(500) = (-14.14, 37.41) \]

Exercise 2: Consider the values in the previous exercise (Exercise 1) above, what is the mean temperature advection in the 750 to 500 hPa layer?

Solution: Only west–east component: \( \nabla \cdot \nabla T = u \frac{\partial T}{\partial x} \quad \frac{\partial T}{\partial x} = -\frac{2^\circ \text{C}}{100 \text{ km}} \)

But temperature in the layer is decreasing \( \implies \frac{\partial T}{\partial x} < 0 \)

Since we are considering a layer, we use mean values:

\[ \text{Temperature advection in the layer} = -\bar{u} \frac{\partial T}{\partial x} \]

where bars denote the means.

\[ \bar{u} = \left( \frac{u_g(500) + u_g(750)}{2} \right) = \frac{-14.14 - 14.14}{2} = -14.14 \text{ m s}^{-1} \]
Therefore, temperature advection in the layer \( \frac{\partial T}{\partial x} = -1.018 \, \text{K h}^{-1} \).

**Bonus Homework:** Describe the relationship between turning of geostrophic wind and temperature advection in terms of backing and veering of the wind with height for the Southern Hemisphere.

**Barotropic and baroclinic atmospheres**

Barotropic atmosphere: \( \rho = \rho(p) \); thermal wind equation \( \frac{\partial V_g}{\partial \ln p} = 0 \), which states that the geostrophic wind is independent of height.

Baroclinic atmosphere: \( \rho = \rho(p, T) \); geostrophic wind has vertical sheer, related to the horizontal temperature gradient.
Vertical motion

In general the vertical velocity component of synoptic-scale motions is not measured directly, but must be inferred from fields that are measured directly.

Two commonly used methods for inferring vertical motion:

1. Kinematic (based on continuity equation)

2. Adiabatic (based on thermodynamic energy equation)

\[ \omega = \omega(p) \] vertical velocity in isobaric coordinates.

\[ \omega \equiv \frac{DP}{Dt} = \frac{\partial p}{\partial t} + u \frac{\partial p}{\partial x} + v \frac{\partial p}{\partial y} + w \frac{\partial p}{\partial z} \]

\[ = \frac{\partial p}{\partial t} + \nabla \cdot \nabla p + w \frac{\partial p}{\partial z} \]

\[ = \frac{\partial p}{\partial t} + (\nabla_g + \nabla_a) \cdot \nabla p - g \rho w \quad \text{(Since } \frac{\partial p}{\partial z} = -\rho g) \]

\( \nabla_a \): Ageostrophic wind, \( |\nabla_a| \ll |\nabla_g| \) the geostrophic wind

\[ \therefore \omega = \frac{\partial p}{\partial t} + \nabla_g \cdot \nabla p + \nabla_a \cdot \nabla p - g \rho w \]

**Bonus Homework**: Show that \( \nabla_g \cdot \nabla p = 0 \) \( (\nabla_g = \frac{1}{\rho f} \mathbf{k} \times \nabla p) \)

\[ \therefore \omega = \frac{\partial p}{\partial t} + \nabla_a \cdot \nabla p - g \rho w \]

(3.37)

**Scale analysis**:

\[ \frac{\partial p}{\partial t} \sim 10 \text{ hPa/day} \quad [1 \text{ hPa} = 100 \text{ Pa}] \]

\[ \nabla_a \cdot \nabla p \sim (1 \text{ m/s})(0.01 \text{ hPa/km}) \sim 1 \text{ hPa/day} \]

\[ g \rho w \sim 100 \text{ hPa/day} \]

Therefore, a good approximation is

\[ \omega = -g \rho w \]

(3.38)
**Kinematic method**

One method of deducing the vertical velocity. Integration of the continuity equation

\[
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial \omega}{\partial p} = 0
\]

with respect to pressure from a reference level \( p_s \) to any level \( p \), yields

\[
w(z) = \frac{\rho(z_w)w(z_s)}{\rho(z)} - \frac{p_s - p}{\rho(z)g} \left( \frac{\partial \langle u \rangle}{\partial x} + \frac{\partial \langle v \rangle}{\partial y} \right),
\]

(3.40)

where \( z \) and \( z_s \) are the heights of pressure levels \( p \) and \( p_s \), respectively.

Derivation of (3.40):

\[
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial \omega}{\partial p} = 0 \implies \frac{\partial \omega}{\partial p} = - \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right)
\]

Integrate this expression with respect to pressure from a reference level \( p_s \) to any level \( p \):

\[
\int_{p_s}^{p} \frac{\partial \omega}{\partial p} dp = - \int_{p_s}^{p} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) dp
\]

\[
\therefore \omega(p) - \omega(p_s) = - \left[ \frac{\partial}{\partial x} \int_{p_s}^{p} u dp + \frac{\partial}{\partial y} \int_{p_s}^{p} v dp \right]
\]

Define a pressure weighted vertical average:

\[
\langle A \rangle \equiv (p - p_s)^{-1} \int_{p_s}^{p} Adp
\]

\[
\therefore \int_{p_s}^{p} Adp = (p - p_s) \langle A \rangle = -(p_s - p) \langle A \rangle
\]

\[
\therefore \omega(p) - \omega(p_s) = - \left[ \frac{\partial}{\partial x} \{ -(p_s - p) \langle u \rangle \} + \frac{\partial}{\partial y} \{ -(p_s - p) \langle v \rangle \} \right]
\]

\[
= (p_s - p) \frac{\partial \langle u \rangle}{\partial x} + (p_s - p) \frac{\partial \langle v \rangle}{\partial y}
\]

\[
\therefore \omega(p) = \omega(p_s) + (p_s - p) \left( \frac{\partial \langle u \rangle}{\partial x} + \frac{\partial \langle v \rangle}{\partial y} \right)
\]

Since \( \omega = -\rho gw \), we get

\[
-w(z) = -\rho(z)gw(z) = -\rho(z_s)gw(z_s) + (p_s - p) \left( \frac{\partial \langle u \rangle}{\partial x} + \frac{\partial \langle v \rangle}{\partial y} \right)
\]

\[
w(z) = \frac{\rho(z_s)w(z_s)}{\rho(z)} - \frac{p_s - p}{\rho(z)g} \left( \frac{\partial \langle u \rangle}{\partial x} + \frac{\partial \langle v \rangle}{\partial y} \right)
\]

To infer the vertical velocity from the equation above requires knowledge of the horizontal divergence:

\[
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y}
\]

Consider the table below showing the \( u \) and \( v \) components of the wind (\( m \cdot s^{-1} \)) for the 200 hPa level, on a 2.5° lat–long grid:
Using finite difference approximations:

\[ \frac{\delta u}{\delta x} = \frac{[(u_{12} + u_{22})/2 - (u_{11} + u_{21})/2]}{\delta x} \]
\[ \frac{\delta v}{\delta y} = \frac{[(v_{11} + v_{12})/2 - (v_{21} + v_{22})/2]}{\delta y} \]
\[ \delta y = 2\pi 6.37 \times 10^6/144; \quad \delta x = \delta y \cos(21.25^\circ) \]

Typical values for \( u \) and \( v \):

\[ u = [28.8 \quad 28.7; \quad 34.6 \quad 37.4] \]
\[ v = [-20.5 \quad -18.2; \quad -26.9 \quad -25.0] \]

An error in one of the wind components can lead to an exponential growth in the estimated divergence. See figure below. For this reason, the continuity equation method is not recommended for estimating the vertical motion field from observed horizontal winds.
Adiabatic method

The adiabatic method for inferring vertical velocities, which is not so sensitive to errors in the measured horizontal velocities, is based on the thermodynamic energy equation:

\[
\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} - S_p \omega = \frac{J}{c_p}
\]  

(3.6)

If \( J \), the diabatic heating, is small:

\[
\omega = \frac{1}{S_p} \left( \frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right)
\]

\[
= \frac{1}{S_p} \left( \frac{\partial T}{\partial t} + \mathbf{V} \cdot \nabla T \right)
\]

The temperature advection \( \mathbf{V} \cdot \nabla T \) can be accurately obtained from geostrophic winds, and so this method can be applied.

However, \( \frac{\partial T}{\partial t} \) is difficult to estimate accurately since observations are not typically at close time intervals.

This method is also inaccurate when \( J \) is not small (i.e., strong diabatic heating) as is the case of storms in which heavy rainfall occurs over a large area.

**Exercise:** For a high altitude station located near the 750 to 500 hPa layer, the temperature is decreasing at a rate of \( 2^\circ \text{C} \) per hour. Compute the vertical velocity in cm/s using the adiabatic method. Suppose the lapse rate at the station is \( 4^\circ \text{C} / \text{km} \), temperature advection is \( -2.828 \times 10^{-4} \text{ K s}^{-1} \), and that the dry adiabatic lapse rate is determined by gravity and by the specific heat of dry air at constant pressure.

**Solution:**

\[
\frac{\partial T}{\partial t} = -2^\circ \text{C h}^{-1} \quad \text{(decreasing)}
\]

Adiabatic method: \( \omega = \frac{1}{S_p} \left( \frac{\partial T}{\partial t} + \mathbf{V} \cdot \nabla T \right) \), \( S_p = \frac{\Gamma_d - \Gamma}{\rho g} \) and \( \omega = -\rho g w \)

\[
\therefore w = \frac{\left( \frac{\partial T}{\partial t} + \mathbf{V} \cdot \nabla T \right)}{\Gamma - \Gamma_d}
\]

\[
\Gamma_d = \frac{g}{c_p} = \frac{9.81 \text{ m s}^{-2}}{1005 \text{ J K}^{-1} \text{ kg}^{-1}} = 9.771 \times 10^{-3} \text{ m s}^{-2} (\text{JK}^{-1} \text{ kg}^{-1})^{-1}
\]

\[
= 9.771 \times 10^{-3} \text{ m s}^{-2} (\text{kg m s}^{-2} \text{ m K}^{-1} \text{ kg}^{-1})^{-1}
\]

\[
= 9.771 \times 10^{-3} \text{ K m}^{-1}
\]

\[
\Gamma = 4 \text{ K m}^{-1} = 4 \times 10^{-3} \text{ K m}^{-1}
\]
\[ w = \frac{\left( -\frac{2}{3600} \text{ K s}^{-1} - 2.828 \times 10^{-4} \text{ K s}^{-1} \right)}{(4 \times 10^{-3} - 9.771 \times 10^{-3}) \text{ K m}^{-1}} \]

\[ = 0.1453 \text{ m s}^{-1} \]

\[ = 14.53 \text{ cm s}^{-1} \]
Surface pressure tendency

The development of a **negative surface pressure tendency** is a classic warning of an **approaching cyclonic weather disturbance**.

\[
\omega(p) = \omega(p_s) - \int_{p_s}^{p} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) dp
\]

(3.39)  

where \( \lim_{p \to 0} \Rightarrow 0 = \omega(p_s) + \int_{0}^{p_s} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) dp \)

\[
\therefore \omega(p_s) = -\int_{0}^{p_s} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) dp
\]

\[
= -\int_{0}^{p_s} (\nabla \cdot \vec{V})dp
\]

(3.43)  

\[
\omega = \frac{\partial p}{\partial t} + \nabla_a \cdot \nabla p - g \rho w
\]

(3.37)  

Assumption: \( w \) at the surface = 0, and \( \nabla_a \cdot \nabla p \) can be neglected (scaling considerations)

\[
\therefore \omega \approx \frac{\partial p}{\partial t}
\]

\[
\therefore \frac{\partial p}{\partial t} \approx -\int_{0}^{p_s} (\nabla \cdot \vec{V})dp
\]

(3.44)  

In words: The surface **pressure tendency** at a given point is determined by the total convergence (negative divergence) of mass into the vertical column of atmosphere above that point.

The utility of the tendency equation is severely limited due to the fact that \( \nabla \cdot \vec{V} \) is difficult to compute from observations because it depends on the ageostrophic wind field.

**Bonus Homework**: Describe qualitatively the origin of surface pressure changes and the relationship of such changes to the horizontal divergence.
The circulation theorem

Circulation about a closed contour in a fluid:

\[ C = \oint (d\mathbf{l} \cdot \mathbf{U}) \]
\[ = 2\Omega \pi R^2 \]
\[ R: \text{radius of circular ring of fluid} \]

\[ \Rightarrow \] the circulation is \( 2\pi \) times the angular momentum of the fluid.

By integrating Newton’s second law, we can obtain the circulation theorem in an absolute coordinate system as:

\[ \frac{dC_a}{Dt} = \frac{D}{Dt} \oint (d\mathbf{l} \cdot \mathbf{U}) = -\oint \frac{1}{\rho} dp \]

The solenoidal term is \( -\oint \frac{1}{\rho} dp \)

In meteorological analysis it is more convenient to work with the relative circulations \( C \).

\[ C = C_a - C_e \]
\[ = C_a - 2\Omega A_e \]
\[ \frac{dC}{Dt} = \frac{dC_a}{Dt} - 2\Omega \frac{DA_e}{Dt} \]
\[ = -\oint \frac{1}{\rho} dp - 2\Omega \frac{DA_e}{Dt} \]
Vorticity

Definition: The microscopic measure of rotation in a fluid. It is a vector field defined as the curl of velocity.

Absolute vorticity \( \omega_a \equiv \nabla \times U_a \)

Relative vorticity \( \omega \equiv \nabla \times \mathbf{U} \) (\( \mathbf{U} \) is the relative velocity)

\[ \therefore \omega = \left( \frac{\partial}{\partial x} + \frac{j}{\partial y} + \frac{k}{\partial z} \right) \times (iu + jv + kw) \]

\[ = \begin{vmatrix}
  \hat{i} & \hat{j} & \hat{k} \\
  \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\
  u & v & w
\end{vmatrix} \]

\[ = \frac{\partial w}{\partial y} \left( \frac{\partial v}{\partial z} - \frac{\partial u}{\partial y} \right) - \frac{\partial w}{\partial x} \left( \frac{\partial v}{\partial z} - \frac{\partial u}{\partial x} \right) + \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) \]

For large-scale dynamic meteorology, the concern is only with the vertical components of absolute and relative vorticity.

Absolute vorticity \( \eta \equiv \mathbf{k} \cdot (\nabla \times U_a) \)

Relative vorticity \( \zeta \equiv \mathbf{k} \cdot (\nabla \times \mathbf{U}) \)

Regions of \( \zeta < 0 \) are associated with cyclonic storms in the Southern Hemisphere.

The distribution of \( \zeta \) is an excellent diagnostic for weather analysis.

Planetary vorticity: the local vertical component of the vorticity of the earth due to its rotation

\[ \mathbf{k} \cdot \nabla \times \mathbf{U}_e = 2\Omega \sin \phi = f \), the Coriolis parameter \]

\[ \eta = \zeta + f \]

\[ \zeta = \mathbf{k} \cdot \left( \frac{\partial w}{\partial y} \frac{\partial v}{\partial z} + \frac{\partial u}{\partial z} - \frac{\partial w}{\partial x} \frac{\partial v}{\partial x} + \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) \]

\[ = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \]

\[ \therefore \eta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} + f \]
Exercise 1: What is the relative vorticity on the side of a current which decreases in magnitude towards the south at a rate of $10 \text{ m/s}$ for every $500 \text{ km}$?

$$\zeta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}$$

No west–east component: $\frac{\partial v}{\partial x} = 0$

$$\frac{\partial u}{\partial y} < 0 \quad \text{(towards the south)}$$

$$\therefore \frac{\partial u}{\partial y} = \frac{-10 \text{ m/s}}{500,000 \text{ m}} = -2 \times 10^{-5} \text{ s}^{-1}$$

$$\therefore \zeta = 0 - (-2 \times 10^{-5} \text{ s}^{-1})$$

$$= 2 \times 10^{-5} \text{ s}^{-1}$$

Exercise 2: An air parcel at $30^\circ \text{S}$ moves southward conserving absolute vorticity (the initial absolute vorticity is equal to the final absolute vorticity). If its initial relative vorticity is $5 \times 10^{-5} \text{ s}^{-1}$, what is its relative vorticity upon reaching $90^\circ \text{S}$?

Solution:

$$(\zeta + f)_{\text{initial}} = (\zeta + f)_{\text{final}}$$

$$f_{\text{initial}} = 2\Omega \sin(-30^\circ) = 2\Omega \left(-\frac{1}{2}\right) = -\Omega$$

$$f_{\text{final}} = 2\Omega \sin(-90^\circ) = 2\Omega (-1) = -2\Omega$$

$$\zeta_{\text{initial}} = 5 \times 10^{-5} \text{ s}^{-1} \quad (\text{given})$$

$$\zeta_{\text{final}} = (\zeta + f)_{\text{initial}} - f_{\text{final}}$$

$$= 5 \times 10^{-5} - \Omega - (-2\Omega)$$

$$= 5 \times 10^{-5} + \Omega$$

$$= 5 \times 10^{-5} + 7.292 \times 10^{-5} \text{ rad s}^{-1}$$

$$= 12.292 \times 10^{-5} \text{ s}^{-1}$$

Bonus Homework: Determine the relationship between relative vorticity and relative circulation (macroscopic).
Potential vorticity

Definition and characteristics of potential vorticity

The potential vorticity (PV) is the absolute circulation of an air parcel that is enclosed between two isentropic surfaces (a surface in space on which potential temperature is everywhere equal). If PV is displayed on a surface of constant potential temperature, then it is officially called IPV (isentropic potential vorticity). PV could also be displayed on another surface, for example a pressure surface. Note from the relation below, that PV is simply the product of absolute vorticity on an isentropic surface and static stability. So PV consists, in contrast to vorticity on isobaric surfaces, of two factors, a dynamical element and a thermodynamical element.

\[
P V \equiv (\zeta_\theta + f) \left(-g \frac{\partial \theta}{\partial p}\right)
\]

where,

- \(f\) is the Coriolis parameter
- \(g\) is the gravitational acceleration
- \(p\) is the pressure
- \(PV\) is the potential vorticity
- \(\theta\) is the potential temperature: \(\theta = T \left(\frac{p_s}{p}\right)^{R/c_p}\)
- \(\zeta_\theta\) is the relative isentropic vorticity [the vertical component of relative vorticity evaluated on an isentropic surface]

Within the troposphere, the values of PV are usually low. However, the potential vorticity increases rapidly from the troposphere to the stratosphere due to the significant change of the static stability. Typical changes of the potential vorticity within the area of the tropopause are from 1 (tropospheric air) to 4 (stratospheric air) PV units (PV unit: 1 PVU = 10^{-6} K kg^{-1} m^2 s^{-1}). Today in most of the literature the 2 PV unit anomaly, which separates tropospheric from stratospheric air, is referred to as dynamical tropopause. The traditional way of describing the tropopause, is with use of the potential temperature or static stability. This is only a thermodynamical way of characterising the tropopause. The benefit of using PV is that the tropopause can be understood in both thermodynamic and dynamic terms. An abrupt folding or lowering of the dynamical tropopause can also be called an upper PV-anomaly. When this occurs, stratospheric air penetrates into the troposphere resulting in high values of PV with respect to the surroundings, creating a positive PV-anomaly.
In the lower levels of the troposphere, strong baroclinic zones often occur which can be regarded as low level PV anomalies.

It must be stressed that this other way of looking at the dynamics of the atmosphere will not necessarily result in new conclusions. However, it may give new dimensions to things that, in fact, were already known.

The two main advantages of potential vorticity (with certain assumptions) are: conservation and invertibility. The two advantages will be discussed briefly:

**Conservation**

With the following assumptions PV is a conserved parameter:

1. Adiabatic stream (no diabatic heating or cooling)
2. No friction
3. Homogenous
4. Non-compressing

A first mathematical consequence of the conservation can be derived from the definition of PV: A parcel will keep the same value of PV if it moves along an adiabat through the atmosphere thus the equation for PV can be written as:

\[
PV \equiv (\zeta_\theta + f) \left(-g \frac{\partial \theta}{\partial p}\right) = \text{constant} \quad (4.12)
\]

Due to the conservation of PV, there is a close relationship between absolute vorticity and static stability (the ability of a fluid at rest to become turbulent or laminar [flow taking place along constant streamlines, without turbulence] due to the effects of buoyancy). The diagram below shows a parcel (cylinder) that is confined between potential temperature (isentropic) surfaces \(\theta\) and \(\theta + \delta\theta\) which are separated by a pressure interval \(\delta p\). Difference in potential temperature between the top and bottom is the same for the two cylinders. If PV is conserved, and the cylinder is stretched, then static stability is decreasing and absolute vorticity must increase. Alternatively, if one goes from the stretched cylinder to the squashed cylinder, then static stability is increasing and absolute vorticity must decrease.

Due to the conservation of PV, significant features that are related to synoptic scale weather systems can be identified and followed in space as well as in time. This is a very powerful characteristic of this property.
Especially the case of a lowering of the dynamical tropopause, the upper PV-anomaly can be followed in time and space rather easily. PV anomalies are well related to a lot of dynamical processes in the troposphere. A distinct example of this are cases of Rapid Cyclogenesis where PV-anomalies play an important role.

The sudden creation or destruction of PV means that diabatic processes are involved (release of latent heat, friction, radiation). This fact can be used as tool to identify or even quantify the influence of these processes.

**Invertibility**

The second advantage of PV, invertibility, is a very important tool, because it allows one to obtain familiar meteorological fields, like the geopotential, wind, temperature and the static stability, when the distribution of the PV and the boundary conditions, potential temperature at the surface, are known. Further with the help of the invertibility it is possible to quantify the importance of PV-anomalies and the strength of their associated circulation and/or temperature pattern.

Inverting the PV for the entire atmosphere is interesting, but a more insightful diagnostic technique is piece-wise PV inversion (PPVI). This involves dividing the atmosphere into significant layers and independently inverting the PV in those layers. This technique allows for analysis of the influence of discreet portions of the total PV field on the flow throughout the domain.

**PV-thinking in the real atmosphere**

**The dynamical tropopause**

The tropopause separates the well-mixed troposphere with the highly stratified, statically stable stratosphere. The tropopause is conventionally thought of from a thermal point of view and is based on the vertical temperature lapse rate. However, since high-PV values are generally associated with highly statically stable air, the tropopause can also be defined by the isentropic (contours of constant potential temperature) gradient of PV. The PV definition of the troposphere is known as the dynamical tropopause. By convention, the dynamical tropopause is usually defined by a constant PV contour which separates tightly packed PV contours of the stratosphere and low vertical gradient PV contours of the troposphere. A value between $-1.5$ and $-2.5$ PVU is most commonly used.
**PV anomalies**

Mathematically, an anomaly is the departure of a value from the mean distribution. A high-PV anomaly will thus be where there are anomalously high values (large negative values in the southern hemisphere) of PV compared to the mean distribution. Conversely, a low-PV anomaly will have anomalously small values (smaller negative values) of PV compared to the mean distribution.

**Upper level PV anomalies**

As seen in Fig. 1, there exists a reservoir of high-PV air in the stratosphere. Thus, stratospheric air is a source of high-PV anomalies in the troposphere. Upper-level high-PV anomalies can therefore be viewed, from a cross-sectional point of view, as tongues of high-PV stratospheric air intruding into the troposphere towards the surface. An idealised example of this is shown in Fig. 2. We recall that the circulation can be inferred from the PV distribution by the power of PV inversion and recall that PV can be represented by equation (4.12). The high-PV (negative PV anomaly) induces a negative vorticity anomaly. Flow is cyclonic around a negative vorticity anomaly in the Southern Hemisphere and hence cyclonic around the high-PV anomaly. Since the atmosphere is in thermal wind balance, the velocity of the circulation above and below the anomaly will also be cyclonic but the flow will be weaker.

The fact that the atmosphere is in thermal wind balance allows for us to decipher the temperature structure of the sectors. Recalling that the definition of the thermal wind is the difference between the upper and lower wind vectors \( \nabla_T = \nabla_g(p_1) - \nabla_g(p_0) \) and that the cold pool lies to the left (right) of the thermal...
wind vector in the Northern (Southern) hemisphere, it follows that there must exist a cold pool below the high-PV anomaly. Similarly, there must exist a warm pool in the stratospheric sector above the high-PV anomaly with cold air surrounding it. Thus, the potential temperature structure will look as below.

**Figure 2:** A cross-sectional view of an idealised PV intrusion in the upper troposphere inducing upper-level cyclonic flow around it.

**Figure 3:** Cross-sectional view of the thermal structure of an idealised PV intrusion in the upper troposphere inducing upper-level cyclonic flow around it.
Low-level and surface PV anomalies

PV anomalies are not confined to the upper troposphere. High-PV structures can also be found in the low levels, often associated with diabatic processes. The PV anomalies act in a similar way to their upper-level counterparts, stimulating cyclonic flow around them. Similar arguments with respect to the thermal balance of the atmosphere can be made in order to understand the thermal structure surrounding the anomaly as well as the cyclonic flow that is induced throughout the atmosphere.

You will recall that for PV to be conserved, the flow must be both frictionless and adiabatic. At the surface, this is not strictly true. Thus, PV cannot be directly used on the surface and we need to use a PV-like parameter to analyse the surface is in a PV-thinking framework. It has been shown that surface potential temperature (θ) anomalies can act as PV-like anomalies. Warm θ anomalies behave in a similar way to high-PV anomalies on the surface where cyclonic flow is stimulated around a warm θ anomaly and anticyclonic flow results from cold θ anomalies.

![Diagram of PV intrusion in the lower troposphere](image)

**Figure 4:** A cross-sectional view of an idealised PV intrusion in the lower troposphere inducing low-level cyclonic flow around it.

Interaction of anomalies

As can be shown schematically in Figure 2 and Figure 3, cyclonic circulation around the upper-level intrusion of high-PV stratospheric air into the upper troposphere is not confined to the upper troposphere. Mirrored, although weaker, cyclogenetic forcing is also present on the surface. As a result of the surface temperature gradient, the low-level cyclogenetic forcing results in warm air temperature advection ahead of the upper-level PV intrusion axis. This results in a warm potential temperature anomaly ahead of the upper-level PV axis. Recall that warm potential temperature anomalies on the surface can be interpreted to be similar to high-PV anomalies whereby they can induce cyclonic circulation around them. The cyclogenetic forcing is induced throughout the troposphere above the anomaly, with mirrored cyclogenetic forcing stimulated ahead of the upper level PV intrusion in the upper-levels. Whilst the surface anomaly lies ahead of the
upper-level anomaly there is positive feedback between the two anomalies and thus are mutually beneficial to one another. Low-level anomalies induced by diabatic processes can further add to the development of the surface cyclone. The phase-locked alignment of all 3 of these anomalies is known as a “PV tower” and can lead to explosive cyclogenesis.

In the atmosphere, these processes lead to the development of baroclinic weather systems such as mid-latitude cyclones or cut-off lows that extend to the surface, where the system leans westward with height.

![Figure 5](image5.png)

**Figure 5:** Adapted from Hoskins et al. (1985). Interaction between an upper air intrusion of high-PV air and an induced surface high-PV anomaly.

**PV on isentropic maps**

Isentropic surfaces, lines of constant potential temperature, are frequently used in the dynamical meteorological analyses. The analysis of isentropic PV has many applications including the identification of Rossby wave breaking (RWB) in the upper troposphere. Upper-level PV intrusions are easily identifiable on isentropic surfaces. Potential temperature contours slant surface-ward from the poles to the equator. Thus, an isentropic contour will cut through the quasi-horizontal dynamical tropopause at some point between the pole and the equator. High-PV values (stratospheric air) will be found towards the poles whilst low-PV values (tropospheric air) will be found towards the equator. A PV anomaly in the upper troposphere can be seen in the isentropic PV field as a tongue of high-PV, stratospheric air extending towards the equator.

![Figure 6](image6.png)

**Figure 6:** Left: Climatological mean isentropic surface of the upper troposphere. Right: An idealised PV intrusion in the upper troposphere as seen on upper-level isentropic PV surface.

The vorticity equation

Objective: Derive an equation for the time rate of change of vorticity without limiting the validity to adiabatic motion.

Cartesian coordinate form

Approximate horizontal momentum equations:

\[
\frac{Du}{Dt} = fv - \frac{1}{\rho} \frac{\partial p}{\partial x} \quad [\text{zonal component equation}]
\]

\[
\frac{Dv}{Dt} = -fu - \frac{1}{\rho} \frac{\partial p}{\partial y} \quad [\text{meridional component equation}]
\]

\[
\frac{\partial}{\partial y} \left( \frac{Du}{Dt} \right) = \frac{\partial}{\partial y} \left( fv \right) - \frac{\partial}{\partial y} \left( \frac{1}{\rho} \frac{\partial p}{\partial x} \right)
\]

\[
\frac{\partial}{\partial x} \left( \frac{Dv}{Dt} \right) = -\frac{\partial}{\partial x} \left( fu \right) - \frac{\partial}{\partial x} \left( \frac{1}{\rho} \frac{\partial p}{\partial y} \right)
\]

and

\[
\frac{\partial}{\partial y} \left( \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} \right) - \frac{\partial}{\partial y} \left( fv \right) = -\frac{\partial}{\partial y} \left( \rho^{-1} \frac{\partial p}{\partial x} \right)
\]

\[
\frac{\partial}{\partial x} \left( \frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} \right) + \frac{\partial}{\partial x} \left( fu \right) = -\frac{\partial}{\partial x} \left( \rho^{-1} \frac{\partial p}{\partial y} \right)
\]

\[
\therefore \: \frac{\partial^2 u}{\partial y \partial t} + \frac{\partial u \partial u}{\partial y \partial x} + u \frac{\partial^2 u}{\partial x \partial y} + \frac{\partial u \partial u}{\partial y \partial y} + v \frac{\partial^2 u}{\partial y^2} + \frac{\partial w \partial u}{\partial y \partial z} + w \frac{\partial^2 u}{\partial y \partial z} - \frac{\partial f}{\partial y} - \frac{\partial v}{\partial y} \]

\[
= -\frac{\partial \rho^{-1} p}{\partial y} - \frac{1}{\rho} \frac{\partial^2 p}{\partial x \partial y} \quad (1)
\]

and

\[
\therefore \: \frac{\partial^2 v}{\partial x \partial t} + \frac{\partial u \partial v}{\partial x \partial x} + u \frac{\partial^2 v}{\partial x \partial x} + \frac{\partial v \partial v}{\partial x \partial y} + \frac{\partial w \partial v}{\partial x \partial z} + w \frac{\partial^2 v}{\partial x \partial z} - \frac{\partial f}{\partial x} - \frac{\partial u}{\partial x} \]

\[
= -\frac{\partial \rho^{-1} p}{\partial x} - \frac{1}{\rho} \frac{\partial^2 p}{\partial x \partial y} \quad (2)
\]
\[ \frac{\partial}{\partial t} \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) + u \frac{\partial}{\partial x} \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) + v \frac{\partial}{\partial y} \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) + w \frac{\partial}{\partial z} \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) + f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + \left[ \frac{\partial u}{\partial x} \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \frac{\partial v}{\partial y} - \frac{\partial w}{\partial x} \frac{\partial u}{\partial x} - \frac{\partial w}{\partial y} \frac{\partial u}{\partial y} \right] + \frac{\partial w}{\partial x} \frac{\partial v}{\partial z} - \frac{\partial w}{\partial y} \frac{\partial u}{\partial z} + v \frac{\partial f}{\partial y} = \frac{\partial y}{\partial x} = \frac{\partial y}{\partial u} \frac{\partial u}{\partial x} \quad y = \rho^{-1} \quad u = \rho \\
\frac{\partial}{\partial x} \rho^{-1} = \frac{\partial}{\partial \rho} \rho^{-1} \frac{\partial \rho}{\partial x} = -\rho^{-2} \frac{\partial \rho}{\partial x} \]

\[ \left(2 - 1\right): \text{LHS} \]

\[ -\frac{\partial \rho^{-1}}{\partial x} \frac{\partial p}{\partial y} - \frac{1}{\rho} \frac{\partial^2 p}{\partial x \partial y} + \frac{\partial \rho^{-1}}{\partial p} \frac{\partial p}{\partial x} + \frac{1}{\rho} \frac{\partial^2 p}{\partial y \partial x} = -(-1)\rho^{-2} \frac{\partial \rho}{\partial x} \frac{\partial p}{\partial y} + (-1)\rho^{-2} \frac{\partial \rho}{\partial y} \frac{\partial p}{\partial x} \]

\[ = \frac{1}{\rho^2} \frac{\partial \rho}{\partial x} \frac{\partial p}{\partial y} - \frac{1}{\rho^2} \frac{\partial \rho}{\partial y} \frac{\partial p}{\partial x} \]

\[ \text{Consider} \]

\[ \frac{\partial u}{\partial x} \frac{\partial v}{\partial x} + \frac{\partial v}{\partial y} \frac{\partial u}{\partial x} - \frac{\partial u}{\partial y} \frac{\partial v}{\partial x} - \frac{\partial v}{\partial y} \frac{\partial u}{\partial y} = \frac{\partial v}{\partial x} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) - \frac{\partial u}{\partial y} \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \]

\[ = \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \]

\[ \text{Since } \zeta = \left( \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) \]

\[ \frac{\partial \zeta}{\partial t} + u \frac{\partial \zeta}{\partial x} + v \frac{\partial \zeta}{\partial y} + w \frac{\partial \zeta}{\partial z} + f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + \zeta \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + \left( \frac{\partial w}{\partial x} \frac{\partial v}{\partial z} - \frac{\partial w}{\partial y} \frac{\partial u}{\partial z} \right) \]

\[ + v \frac{\partial f}{\partial y} = \left( \frac{\partial \rho}{\partial x} \frac{\partial p}{\partial y} - \frac{\partial \rho}{\partial y} \frac{\partial p}{\partial x} \right) \]

\[ \text{Since } f = f(y), \frac{D f}{D t} = 0 + 0 + v \frac{\partial f}{\partial y} + 0 \]

\[ \therefore \frac{D \zeta}{D t} + (\zeta + f) \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + \left( \frac{\partial w}{\partial x} \frac{\partial v}{\partial z} - \frac{\partial w}{\partial y} \frac{\partial u}{\partial z} \right) + \frac{D f}{D t} = \frac{1}{\rho^2} \left( \frac{\partial \rho}{\partial x} \frac{\partial p}{\partial y} - \frac{\partial \rho}{\partial y} \frac{\partial p}{\partial x} \right) \]

\[ \implies \frac{D}{D t} (\zeta + f) = - (\zeta + f) \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) - \left( \frac{\partial w}{\partial x} \frac{\partial v}{\partial z} - \frac{\partial w}{\partial y} \frac{\partial u}{\partial z} \right) + \frac{1}{\rho^2} \left( \frac{\partial \rho}{\partial x} \frac{\partial p}{\partial y} - \frac{\partial \rho}{\partial y} \frac{\partial p}{\partial x} \right) \quad (4.17) \]

The rate of change of absolute vorticity following the motion is given by the sum of the divergence, the tilting or twisting, and the solenoidal terms.
Scale analysis of the vorticity equation

Characteristic scales for the field variables based on typical observed magnitudes for synoptic-scale motions:

\[
\begin{align*}
U & \sim 10 \text{ m s}^{-1} & \text{horizontal scale} \\
W & \sim 1 \text{ cm s}^{-1} & \text{vertical scale} \\
L & \sim 10^6 \text{ m} & \text{length scale} \\
H & \sim 10^4 \text{ m} & \text{depth scale} \\
\delta p & \sim 10 \text{ hPa} & \text{horizontal pressure scale} \\
\rho & \sim 1 \text{ kg m}^{-3} & \text{mean density} \\
\delta \rho / \rho & \sim 10^{-2} & \text{fractional density fluctuation} \\
L/U & \sim 10^5 \text{ s} & \text{time scale} \\
f_0 & \sim 10^{-4} \text{ s}^{-1} & \text{Coriolis parameter} \\
\beta & \sim 10^{-11} \text{ m}^{-1} \text{ s}^{-1} & \text{“beta” parameter}
\end{align*}
\]

Use an advective time scale because the vorticity pattern tends to move at a speed comparable to the horizontal wind speed.

First, the relative vorticity equation \( \zeta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \lesssim \frac{U}{L} \sim (10^5 \text{ s})^{-1} = 10^{-5} \text{ s}^{-1} \)

[\lesssim \text{ means less than or equal to in order of magnitude}]

The magnitude of the terms of the equation below will be evaluated:

\[
\begin{align*}
\frac{\partial \zeta}{\partial t} + u\frac{\partial \zeta}{\partial x} + v\frac{\partial \zeta}{\partial y} + w\frac{\partial \zeta}{\partial z} + (\zeta + f) \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + \left( \frac{\partial w}{\partial x} \frac{\partial v}{\partial z} - \frac{\partial w}{\partial y} \frac{\partial u}{\partial z} \right) + \frac{v df}{dy} &= \frac{1}{\rho^2} \left( \frac{\partial \rho}{\partial x} \frac{\partial p}{\partial y} - \frac{\partial \rho}{\partial y} \frac{\partial p}{\partial x} \right)
\end{align*}
\]

The Rossby number \( Ro \equiv \frac{U}{f_0L} \)

and since \( \zeta \lesssim \frac{U}{L} \cdot \frac{\zeta}{f_0} \lesssim \frac{U}{f_0L} \sim 10^{-1} \quad \left[ 10 \text{ m} \cdot \text{s}^{-1} / (10^4 \text{ s}^{-1} 10^6 \text{ m}) \right] \)

\[ \therefore \zeta \sim \frac{1}{10} f_0 \]

\[ \therefore (\zeta + f) \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \approx f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \]

Note: Small Ro signifies a system which is strongly affected by Coriolis forces, and a large Ro a system in which inertial and centrifugal forces dominate. In tornadoes \( Ro \approx 10^3 \); in low pressure systems \( Ro \approx 0.1 \sim 1 \).

Near the centre of intense cyclonic storm \( \left| \frac{\zeta}{f} \right| \sim 1 \), the relative vorticity should be retained.
\[
\frac{\partial \zeta}{\partial t} \sim \frac{U/L}{L/U} = \frac{U^2}{L^2} \sim 10^{-10} s^{-2} \quad \left[ \frac{(10 \text{ m s}^{-1})^2}{(10^6 \text{ m})^2} = 10^{-10} s^{-2} \right]
\]

\[
u \frac{\partial \zeta}{\partial x} \sim \frac{U}{L} \frac{U}{L} = \frac{U^2}{L^2}
\]

\[
v \frac{\partial \zeta}{\partial y} \sim \frac{U}{L} \frac{U}{L} = \frac{U^2}{L^2}
\]

\[
w \frac{\partial \zeta}{\partial z} \sim \frac{W}{L} \frac{1}{H} \sim \frac{10^{-2} \text{ m s}^{-1} 10 \text{ m s}^{-1}}{10^6 \text{ m} 10^4 \text{ m}} = 10^{-11} s^{-2}
\]

\[
v \frac{df}{dy} \sim U \beta \sim 10 \text{ m s}^{-1} 10^{-11} \text{ m}^{-1} \text{ s}^{-1} = 10^{-10} s^{-2}
\]

\[
\begin{align*}
\left\{ f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) &\lesssim f_0 \left( \frac{U}{L} + \frac{U}{L} \right) \sim f_0 \frac{U}{L} \sim 10^{-4} s^{-1} 10 \text{ m s}^{-1} 10^{-6} \text{ m}^{-1} = 10^{-9} s^{-2} \\
\left( \frac{\partial w}{\partial z} - \frac{\partial w}{\partial y} \frac{\partial w}{\partial x} \right) &\lesssim \frac{W U}{L H} \sim \frac{10^{-2} \text{ m s}^{-1} 10 \text{ m s}^{-1}}{10^6 \text{ m} 10^4 \text{ m}} = 10^{-11} s^{-2} \\
\left( \frac{1}{\rho^2} \left( \frac{\partial \rho}{\partial y} \frac{\partial \rho}{\partial x} - \frac{\partial \rho}{\partial x} \frac{\partial \rho}{\partial y} \right) \right) &\lesssim \frac{1}{\rho^2} \left( \frac{\delta \rho \delta p}{L^2} \right) = \frac{\delta \rho \delta p}{\rho^2 L^2} \sim \frac{10^{-2} \text{ hPa}}{10^{12} \text{ m}^2} \sim 10^{-2} 10^3 \text{ Pa} \sim 1 \text{ kg m}^{-3} 10^{12} \text{ m}^2
\end{align*}
\]

Consider

\[
1 \text{ Pa} = 1 \text{ N m}^2 = 1(\text{kg m s}^{-2}) \text{ m}^{-2}
\]

\[
\therefore \frac{\delta \rho \delta p}{\rho^2 L^2} \sim 10^{-11} \frac{\text{kg m}^{-1} \text{s}^{-2}}{\text{kg m}^{-1}} = 10^{-11} s^{-2}
\]

(*) The inequality (\lesssim) is used here because in each case it is possible that the two parts of the expression might partially cancel so that the actual magnitude would be less than indicated.

If \( \frac{\partial u}{\partial x} \) and \( \frac{\partial v}{\partial y} \) are not nearly equal and opposite (i.e., divergence > 0) the divergence term would be an order of magnitude greater than the other terms (because \( f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \lesssim 10^{-9} s^{-2} \), followed by terms \( \lesssim 10^{-10} \) and smaller).

Therefore, scale analysis of the vorticity equation indicates that synoptic-scale motions must be quasi-nondivergent. The divergence term will be small enough to be balanced by the vorticity advection terms only if:

\[
\left| \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \right| \lesssim 10^{-6} \text{ s}^{-1} \quad \text{since } f_0 \sim 10^{-4} \text{ s}^{-1}, f_0 \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \sim 10^{-10} s^{-2}
\]

\[\implies \] The horizontal divergence must be small compared to the vorticity in synoptic-scale systems.

Retaining only the terms of order \( 10^{-10} s^{-2} \) in the vorticity equation:

\[
\frac{\partial \zeta}{\partial t} + u \frac{\partial \zeta}{\partial x} + v \frac{\partial \zeta}{\partial y} + f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + v \frac{df}{dy} = 0
\]
Remember that \( v \frac{df}{dy} = \frac{Df}{Dt} \) and for horizontal motion \( v \frac{df}{dy} = \frac{D_h f}{Dt} \).

\[
\therefore \frac{D_h \zeta}{Dt} + f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) + \frac{D_h f}{Dt} = 0 \quad \left[ \frac{D_h}{Dt} = \frac{\partial}{\partial t} + u \frac{\partial}{\partial x} + v \frac{\partial}{\partial y} \right]
\]

\[
\Rightarrow \frac{D_h}{Dt} (\zeta + f) = -f \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \quad (4.22a)
\]

for synoptic-scale motions.

In intense cyclonic storms \( |\zeta/f| \sim 1 \):

\[
\Rightarrow \frac{D_h}{Dt} (\zeta + f) = -(\zeta + f) \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) \quad (4.22b)
\]

Equation (4.22a) states that the change of absolute vorticity following the horizontal motion on the synoptic scale is given approximately by the concentration or dilution of planetary vorticity caused by the convergence or divergence of the horizontal flow, respectively. In (4.22b), however, it is the concentration or dilution of absolute vorticity that leads to changes in absolute vorticity following the motion.

The form of the vorticity equation given in (4.22b) also indicates why cyclonic disturbances can be much more intense than anticyclones. For a fixed amplitude of convergence, relative vorticity will increase, and the factor \((\zeta + f)\) becomes larger, which leads to even higher rates of increase in the relative vorticity. For a fixed rate of divergence, however, relative vorticity will decrease, but when \(\zeta \to -f\), the divergence term on the right approaches zero and the relative vorticity cannot become more negative no matter how strong the divergence (This difference in the potential intensity of cyclones and anticyclones was discussed in Section 3.2.5 of Holton 4 in connection with the gradient wind approximation).

The approximate forms given in (4.22a) and (4.22b) do not remain valid, however, in the vicinity of atmospheric fronts. The horizontal scale of variation in frontal zones is only \( \sim 100 \text{ km} \) and the vertical velocity scale is \( \sim 10 \text{ cm s}^{-1} \). For these scales, vertical advection, tilting, and solenoidal terms all may become as large as the divergence term.
Vorticity in barotropic fluids

The barotropic (Rossby) potential vorticity equation

The velocity divergence form of the continuity equation:

$$\frac{1}{\rho} \frac{D\rho}{Dt} + \nabla \cdot \mathbf{V} = 0$$  \hspace{1cm} (2.31)

For a homogeneous incompressible fluid $\frac{D\rho}{Dt} = 0$

$$\therefore \nabla \cdot \mathbf{V} = 0$$

$$\therefore \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0$$

$$\therefore \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = -\frac{\partial w}{\partial z}$$

$$\therefore \frac{Dh}{Dt}(\zeta + f) = -(\zeta + f) \left( -\frac{\partial w}{\partial z} \right)$$

In a barotropic fluid, we let the vorticity be approximated by $\zeta_g$ and the wind by $(u_g, v_g)$.

$$\frac{Dh}{Dt}(\zeta_g + f) = (\zeta_g + f) \frac{\partial w}{\partial z}$$

Integrate vertically from $z_1$ to $z_2$:

$$\int_{z_1}^{z_2} \frac{Dh}{Dt}(\zeta_g + f)dz = \int_{z_1}^{z_2} (\zeta_g + f) \frac{\partial w}{\partial z}dz$$

$$h \frac{Dh}{Dt}(\zeta_g + f) = (\zeta_g + f) [w(z_2) - w(z_1)]$$

where $h = h(x, y, t); \quad w = \frac{Dz}{Dt}$

$$= z_2 - z_1$$

$$\therefore w(z_2) - w(z_1) = \frac{Dz_2}{Dt} - \frac{Dz_1}{Dt} = \frac{Dh}{Dt}$$
Since \( h \frac{Dh}{Dt} (\zeta + f) = (\zeta + f) [w(z_2) - w(z_1)] = (\zeta + f) \frac{Dh}{Dt} \)

\[ \therefore \frac{1}{(\zeta + f)} \frac{Dh}{Dt} (\zeta + f) = \frac{1}{h} \frac{Dh}{Dt} \]

\[ \therefore \frac{Dh}{Dt} (\ln(\zeta + f)) - \frac{Dh}{Dt} (\ln h) = 0 \]

\[ \therefore \frac{Dh}{Dt} \left( \frac{\zeta + f}{h} \right) = 0 \]

which is the potential vorticity conservation theorem for a barotropic fluid.

The quantity conserved following the motion in (4.26) is the Rossby potential vorticity.

Note the following:

\[ \frac{D}{Dt} (\ln(\zeta + f)) - \frac{D}{Dt} (\ln h) = 0 \]

Therefore,

\[ \frac{D}{Dt} (\ln(\zeta + f) - \ln h) = 0 \]

\[ \therefore \frac{D}{Dt} \left( \ln \left( \frac{\zeta + f}{h} \right) \right) = 0 \]

From calculus: \( Dx \ln[f(x)] = \frac{f'(x)}{f(x)} \)

\[ \implies \frac{D}{Dt} \left( \ln \left( \frac{\zeta + f}{h} \right) \right) = \frac{1}{\zeta + f} \frac{D}{Dt} \left( \frac{\zeta + f}{h} \right) = 0 \]

\[ \therefore \frac{D}{Dt} \left( \frac{\zeta + f}{h} \right) = 0 \]

**Exercise:** By considering the essence of potential vorticity (a measure of the constant ratio of the absolute vorticity to the effective depth of the vortex), an air column at 60°S with initial relative vorticity equal to zero, stretches from sea-level to a fixed tropopause level of 10 km in height. If the air column moves until it is over a mountain range 2.5 km high at 45°S, what is its 1) absolute vorticity and 2) relative vorticity as it passes the mountain top?

**Solution:**

\[ \frac{\zeta + f}{H} = \text{constant} \implies \left( \frac{\zeta + f}{H} \right)_{\text{initial}} = \left( \frac{\zeta + f}{H} \right)_{\text{final}}, \text{ and } \zeta_{\text{initial}} = 0 \text{ (given)} \]

\[ f_{\text{initial}} = 2\Omega \sin(-60°) = -1.263 \times 10^{-4} \text{ s}^{-1} \]

\[ f_{\text{final}} = 2\Omega \sin(-45°) = -1.031 \times 10^{-4} \text{ s}^{-1} \]

\[ \therefore (\zeta + f)_{\text{final}} = \frac{H_{\text{final}}}{H_{\text{initial}}} f_{\text{initial}} \]

\[ = \frac{10 - 2.5}{10} \times (-1.263 \times 10^{-4}) \]

\[ = -9.473 \times 10^{-5} \text{ s}^{-1} \]
The barotropic vorticity equation

\[ \frac{D_b}{Dt} (\zeta + f) = (\zeta + f) \frac{\partial w}{\partial z} \]

If the flow is purely horizontal, as is the case for barotropic flow in a fluid of constant depth, the divergence term vanishes since \( w = 0 \).

As before, let vorticity be approximated by \( \zeta_g \):

\[ \frac{D_b}{Dt} (\zeta_g + f) = 0 \]

which states that absolute vorticity is conserved following the horizontal motion.

More generally, absolute vorticity is conserved for any fluid layer in which the divergence of the horizontal wind vanishes, without the requirement that the flow be geostrophic.

For horizontal motion that is nondivergent the flow can be represented by a stream function \( \psi(x, y) \) such that \( u = -\frac{\partial \psi}{\partial y} \) and \( v = \frac{\partial \psi}{\partial x} \).

\[ \zeta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} = \frac{\partial}{\partial x} \left( \frac{\partial \psi}{\partial x} \right) - \frac{\partial}{\partial y} \left( \frac{\partial \psi}{\partial y} \right) = \frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} = \nabla^2 \psi \]

Not a requirement for flow to be geostrophic: \( \frac{D_b}{Dt} (\zeta + f) = 0 \)

\[ \therefore \frac{\partial \zeta}{\partial t} + u \frac{\partial \zeta}{\partial x} + v \frac{\partial \zeta}{\partial y} + \frac{\partial f}{\partial t} + u \frac{\partial f}{\partial x} + v \frac{\partial f}{\partial y} = 0 \]

\[ \therefore \frac{\partial}{\partial t} \nabla^2 \psi + \nabla \psi \cdot \nabla (\nabla^2 \psi) + \nabla \psi \cdot \nabla (f) = 0; \quad \nabla \psi = \mathbf{k} \times \nabla \psi \]

\[ \frac{\partial}{\partial t} \nabla^2 \psi = -\nabla \psi \cdot \nabla (\nabla^2 \psi + f) \quad (4.28) \]

\[ \Longrightarrow \text{The local tendency of relative vorticity is given by the advection of absolute vorticity.} \]

Because the flow in the mid-troposphere is often nearly nondivergent on the synoptic scale, (4.28) provides a good model for short-term forecasts of the synoptic-scale 500 hPa flow field.
