

OPINION PIECE

DNA Day: UP expert on how DNA technology is changing the face of cancer

By Professor Annie Joubert, Head of the Department of Physiology at the University of Pretoria

DNA Day on 25 April is an opportunity to recognise scientific accomplishments and acknowledge that the vast amount of knowledge available today will lead to tomorrow's discoveries – which will ultimately contribute to our health and well-being, especially in the fight against cancer.

Many may think back to 1953, when the DNA structure discovered by Francis Crick, James Watson, Maurice Wilkins and Rosalind Franklin was published in the journal *Nature*. April is also a significant month because the international Human Genome Project – which took 13 years to finalise – was declared complete on 14 April 2003.

Humans have between 20 000 and 25 000 genes; however, not all genes code for proteins. Cancer is ultimately a disease of DNA – mutations in your genome influence your risk of being diagnosed with it and may determine what happens during the course of the disease. The advent of modern DNA technologies, and particularly next-generation sequencing, is rapidly changing the face of this illness, diagnostics and treatment.

The possibility of screening for DNA mutations in genes that may increase the risk of cancer, especially breast cancer, is advancing with the production of panel testing kits, some of which can target hundreds of genes. There is no doubt that the development and roll-out of these tests will save lives.

Today the complete genome sequence of a cancer patient together with the profile of genes being activated and deactivated can be obtained. This genomic picture can be used to assess a patient's cancer risk, progression and design tailor-made treatment strategies.

There are two approaches to analysing mutations in DNA: tests that analyse the mutations a person was born with and which assess the risk of being diagnosed with cancer (germline cancer susceptibility analysis); and tests that analyse the mutations in tumours or other sources in cancer patients (somatic mutation analysis). Cancer susceptibility analysis may help to determine whether someone should be examined for cancer more regularly with additional screening tests, whereas somatic mutation tests may help oncologists understand what happened when cancer developed and guide them in further testing and treatment.

The genome may be studied for mutations using different approaches. Targeted chip-based analyses report the status of mutations only in positions previously known to be important. This includes testing for mutations at genome sites known to increase cancer risk, mutations related to the prediction of cancer outcome or mutations that guide oncologists in designing the best treatment approach.

When evaluating the genome sequence of an individual, next-generation DNA sequencing approaches are used, and novel or previously less-studied mutations may also be detected. These types of approaches include whole genome sequencing (all DNA), whole exome sequencing (sequencing the sections of the genome that make proteins) and targeted sequencing (where genes or other non-protein-producing, but important, parts of the genome are selectively sequenced).

An additional type of analysis includes whole transcriptome sequencing where messenger RNA molecules (which act from DNA to create a template for the production of a protein molecule) are sequenced and quantified to determine which genes are abnormally active or inactive. Also, duplications of sections in the genome can be analysed in the form of copy number variation, where the duplication of certain genes may lead to cancer.

Breast cancer is one of the most common forms of the disease in women – the lifetime risk of South African women getting breast cancer is one in 27. The role of many mutations in the BRCA1 and BRCA2 genes in breast cancer susceptibility has been well studied. These genes produce proteins that are involved in processes that repair errors that occur in DNA. If they do not function correctly, these errors may lead to the development of cancer. Many other genes also play a role in determining the risk of breast cancer, albeit with smaller effects than BRCA genes. About 15 genes that have mutations more often than expected in women who are diagnosed with breast cancer have been identified. However, hundreds of other genes potentially play a role. In some instances, mutations do not act alone but lead to cancer only when they occur in concert with mutations in other genes.

The possibility of screening for DNA mutations in genes that may increase the risk of breast cancer is rapidly advancing as scientific companies are producing cancer panel testing kits, such as the Illumina TruSight cancer panel developed with Cancer UK, which analyses the sequences of 94 important cancer susceptibility-related genes (not only for breast cancer) and monitors for a series of other possible mutations that have been related to an increased risk of cancer. This is one of the smaller testing kits; others target hundreds of genes. There are also kits that may determine the specific mutations that took place in the tumour of cancer patients, as well as those that do not focus on the DNA sequence per se, but assess abnormal protein expression levels. The MammaPrint breast cancer assay analyses the levels of 70 different gene products that are used to help determine whether a patient should proceed with chemotherapy.

For individuals, access to advanced testing is typically through a cancer centre or an oncologist, who will arrange for a pathology company or specialised DNA analysis company to analyse samples, followed by subsequent consultations with an oncologist and a genetic counsellor. While a few years ago only BRCA1 and BRCA2 testing was commonly available, cancer centres – particularly in the USA, Europe and Asia – are now making regular use of large cancer susceptibility and somatic mutation testing panels. International consortia are building huge databases of mutations in cancer patients and correlating the mutations to the choice of successful treatment methods.

As with most cutting-edge technologies, many of the new testing approaches are costly, not yet commonly available, have not yet been approved for clinical use in all countries, are not part of health insurers' benefits and are sometimes available only to patients that are included in large research trials. Still, the rapid development and roll-out of these tests save are starting to save lives.

About 5 to 10% of cancers can be attributed to genetic inheritance. DNA mutations may occur for several other reasons **after birth**. These mutations may be triggered by risk factors such as tobacco products, alcohol consumption, diet, environmental pollutants, ultraviolet radiation, reproductive and hormonal factors, occupational exposures and infection-attributable cancers.

As Richard Dawkins said, 'DNA neither cares nor knows. DNA just is. And we dance to its music.' The dance between DNA and genomic research impacts our lives hugely. Advances in genomic research reveal the biology of disease and ultimately contribute to redefining our health management today and in the future.

-Ends-

Media enquiries:

Professor Annie Joubert is head of the Department of Physiology at the University of Pretoria. Her research focus is cancer cellular physiology. She studies cancer drug design and cancer cell signalling to identify targets for therapeutic intervention in the fight against cancer.

Please contact Mmane Boikanyo at 082-566-6073 or via mmane.boikanyo@up.ac.za to request an interview.

ABOUT THE UNIVERSITY OF PRETORIA

The University of Pretoria (UP) is one of the largest contact and residential universities in South Africa, with its administration offices located on the Hatfield Campus, Pretoria. This 112-year-old institution is also the largest producer of research in South Africa.

Spread over seven campuses, it has nine faculties and a business school, the Gordon Institute of Business Science (GIBS). It is the only university in the country that has a Faculty of Veterinary Science which is ranked top in Africa, and overall has 120 academic departments, as well as 92 centres and institutes, accommodating more than 55 000 students and offering about 1 100 study programmes.

UP is one of the top five universities in South Africa, according to the 2019-2020 rankings by the Center for World University Rankings. It is also ranked among the top 100 universities worldwide in three fields of study (veterinary science, theology and law), and among the top 1% in eight fields of study (agricultural sciences, clinical medicine, engineering, environment/ecology, immunology, microbiology, plant and animal sciences and social sciences).

In June 2019, the annual UK Financial Times Executive Education Rankings once again ranked GIBS as the top South African and African business school. The University also has an extensive community engagement programme with approximately 33 000 students involved in community upliftment. Furthermore, UP is building considerable capacities and strengths for the Fourth Industrial Revolution by preparing students for the world beyond university and offering work-readiness and entrepreneurship training to its students.

As one of South Africa's research-intensive universities, UP launched the *Future Africa Campus* in March 2019 as a hub for inter- and transdisciplinary research networks within UP and the global research community to maximise 4IR innovation and address the challenges and stresses our continent and world is facing. In addition, UP also launched the Javett Art Centre in September 2019 as a driver of transdisciplinary research development between the Humanities and other faculties. In 2020 UP will launch Engineering 4.0. as a hub not only for Smart Cities and Transport, but also to link the vast resources in technology and data sciences to other faculties via Future Africa. These initiatives are stimulating new thinking at the frontier of 'science for transformation'.
