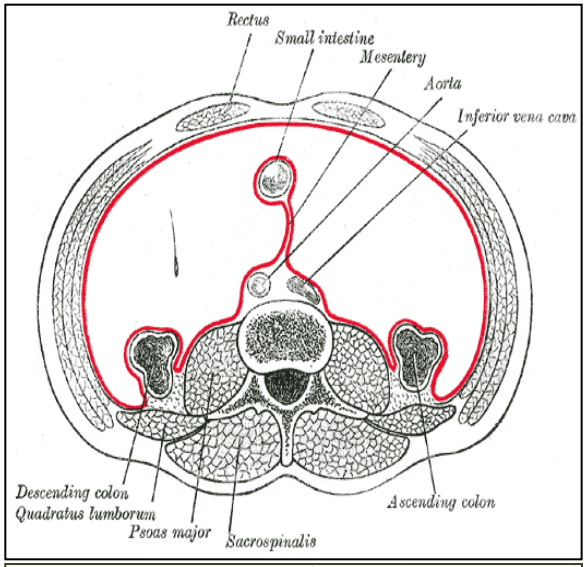
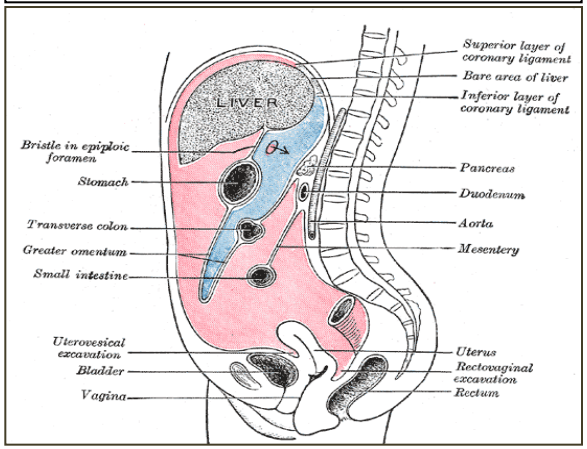
PATHOFYSIOLOGY

PERITONEAL CARCINOMATOSIS : WHY IS PSM DIFFERENT ?





THEORETICAL PATTERNS OF TUMOR SPREAD

- Direct tumor growth
- Lymfovascular spread
- Exfoliation of tumor cells

Steps in the peritoneal metastatic cascade

1. Liberation of cells from tumor mass
2. Transport throughout the peritoneal cavity
3. Adhesion and invasion
4. Systemic spread

PERITONEAL CARCINOMATOSIS : PATHOPHYSIOLOGY

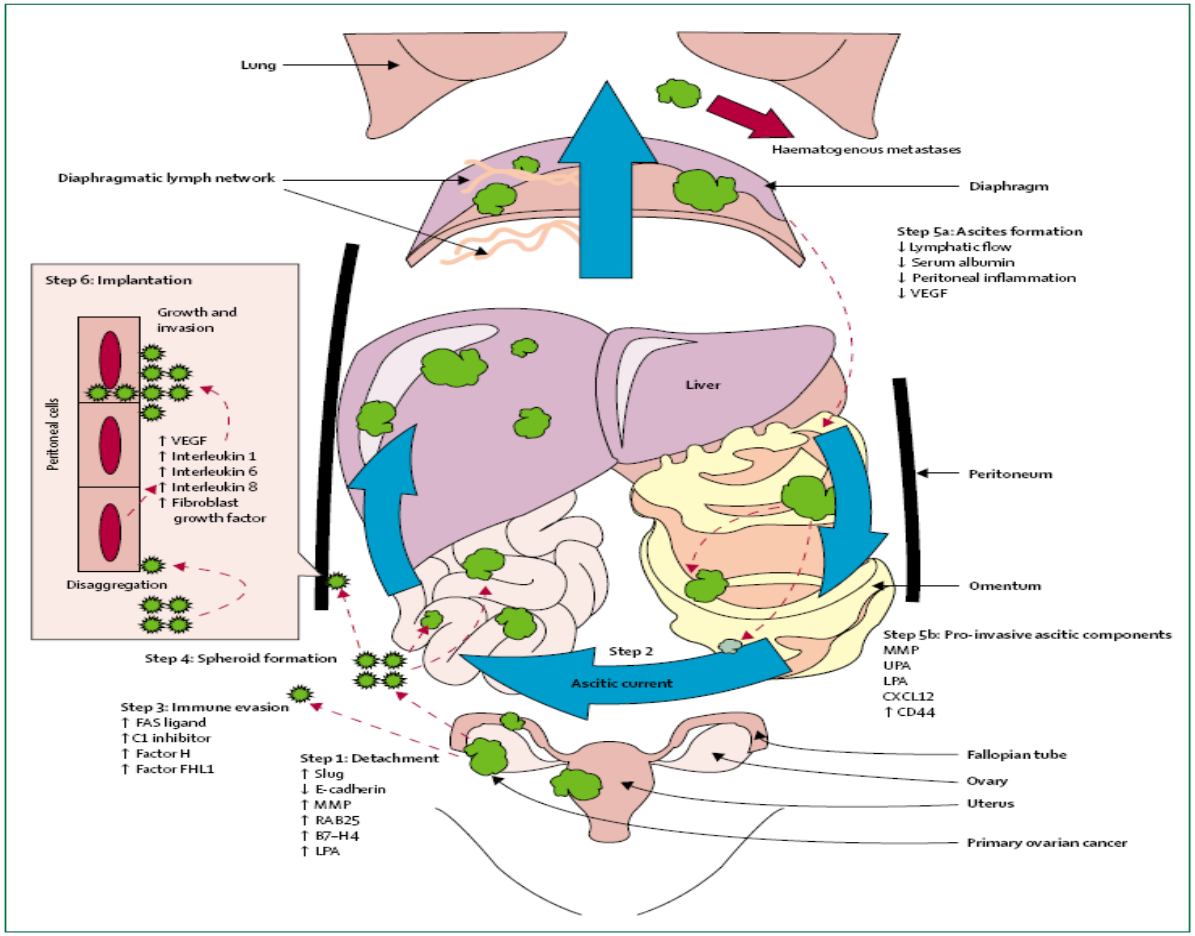


Figure 2: **Mechanisms of transcoelomic metastasis in ovarian cancer**
Step 1: Epithelial ovarian cancer cell (green) detaches after altered gene expression. Step 2: peritoneal or ascitic current (blue arrows) facilitates peritoneal, lymphatic, and haematogenous metastasis. Step 3: immune evasion by complement inhibition and secretion of FAS ligand. Step 4: spheroid formation. Step 5: ascitic components stimulate further metastastic progression. Step 6: peritoneal activation and implantation. B7-H4= Immune costimulatory protein B7-H4; CXCL12=ligand of chemokine (CXC motif) receptor 4 (CXCR4); FHL1= factor H-like protein 1; LPA=lysophosphatidic acid; MMP=matrix metallopeptidase; VEGF=vascular endothelial growth factor.

Pharmacokinetic rationale

"***the peritoneal permeability of a number of hydrophylic anticancer drugs after intraperitoneal administration may be considerably less than the plasma clearance of that same drug***"

- pharmacokinetic principle of **DOSE INTENSIFICATION**
- function of molecular weight
- two compartment model

Dedrick RL et al. Cancer Treat Rep 1978; 62(1):673-88.

DOSE INTENSIFICATION

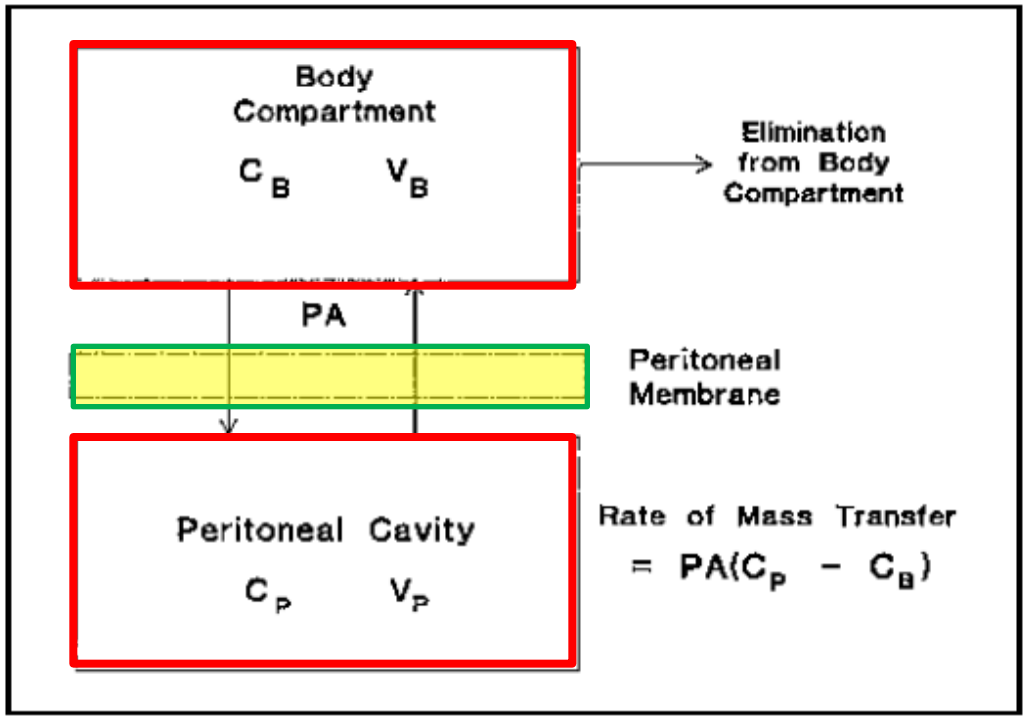

Fig. 1. Traditional two-compartment model of peritoneal transport, in which transfer of a drug from the peritoneal cavity to the blood occurs across the ''peritoneal membrane.'' The permeability-area product (PA) governs this transfer and can be calculated by measuring the rate of drug disappearance from the cavity and dividing by the overall concentration difference between the peritoneal cavity and the blood (or plasma). C_B = the free drug concentration in the blood (or plasma); V_B = volume of distribution of the drug in the body; C_p = the free drug concentration in the peritoneal fluid; V_p = volume of the peritoneal cavity.

Rate of mass transfer = PA (C_P – C_B)

Journal of the National Cancer Institute, Vol. 89, No. 7, April 2, 1997

Question : is ‘ P ‘ influenced by our surgery ?

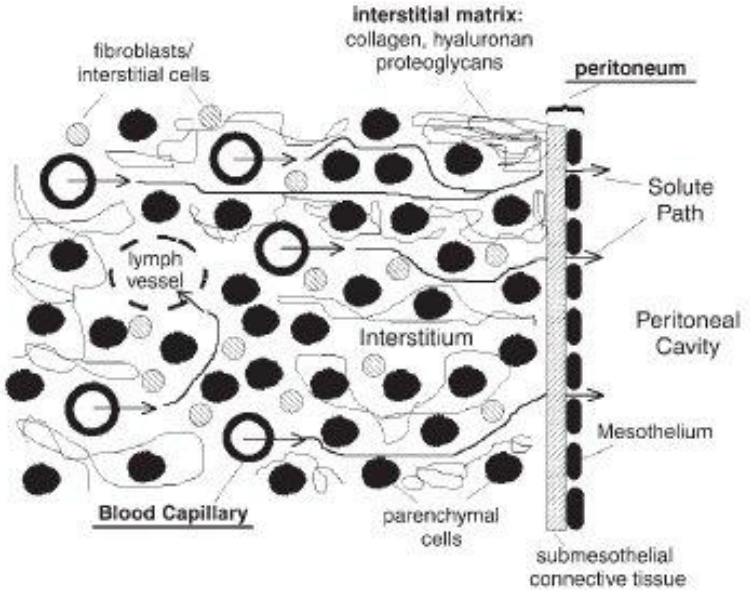

Fig. 1. Peritoneal barrier modeled as blood and lymph capillaries distributed within a tissue space made up of parenchymal cells, interstitial cells, and matrix molecules. The peritoneum, made up of a single layer of mesothelial cells and underlying connective tissue, separates the fluid in the cavity from the underlying tissue space but does not provide a significant barrier to transport. The major resistances to transport are the capillary endothelium and the cell-matrix system surrounding the exchange vessels.

Question : is P influenced by our surgery ?

Peritoneal Barrier Function

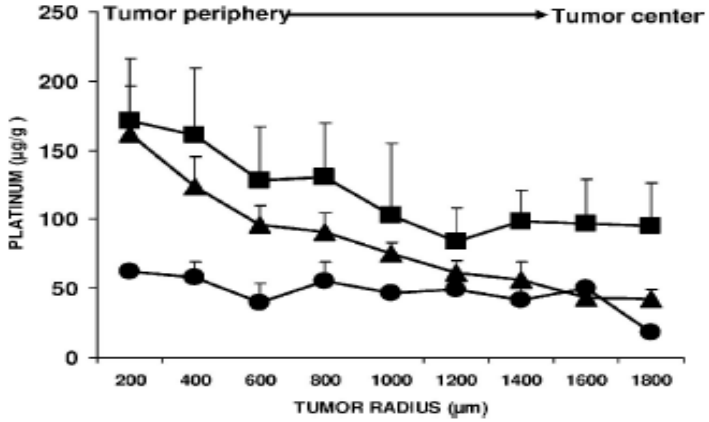

FIGURE 3. Distribution of platinum into peritoneal tumor nodules after conventional IP or IAP cisplatin treatment. Rats with 21-day-old carcinomatosis (4 per group) were treated with cisplatin through a conventional intraperitoneal injection (IP) or an intraperitoneal infusion with increased intra-abdominal pressure (22 mm Hg for 1 hour; IAP). Local platinum concentration was measured along the radii of peritoneal tumor nodules by the PIXE method. The platinum distribution in 400 × 800 μm^2 analyzed areas was plotted from the periphery to the tumor center. In conventionally treated IP groups, the cisplatin concentration in the peritoneal liquid was either 250 mg/L in 20 mL isotonic saline (5 mg/rat; 15 mg/kg; ●), or 1875 mg/L in 20 mL isotonic saline (37.5 mg/rat; 112.5 mg/kg; ▲) to compare groups exposed to the same concentration or the same total dose of cisplatin. Cisplatin concentration was 250 mg/L in 150 mL isotonic saline (37.5 mg/rat; 112.5 mg/kg) for the IAP-treated group (■). Each point is the mean of 4 determinations ± SD. A significant difference among the 3 IP treatments was detected ($P = 0.0125$, Kruskal-Wallis test). The Mann-Whitney test indicated that the difference between both of the upper curves was only significant between a depth of 1400 and 1800 µm ($P = 0.0421$).

Laparoscopic HIPEC: initial experience; opportunities and limitations

Kurt GF Van der Speeten, M.D
Departement of Digestive Surgery, Ziekenhuis Oost-Limburg, Genk - Belgium

Ziekenhuis Oost-Limburg

Introduction

Peritoneal carcinomatosis is a common manifestation of colorectal tumors and is second to metastatic liver disease as cause of death. 25% of patients with peritoneal involvement have no systemic metastasis (1). In the last two decades aggressive resection of all macroscopic peritoneal carcinomatosis, followed by hyperthermic intraperitoneal peroperative chemotherapy (HIPEC) established itself as a new treatment modality with encouraging results (2-3). Until now this technique required an extensive laparotomy for full exploration and peritonectomy. The possibility of performing a laparoscopic peritonectomy and HIPEC was recently explored in an animal model (4). We report the first clinical case of laparoscopic assisted peritonectomy and HIPEC in a patient with limited peritoneal metastasis of an appendiceal carcinoma. The main objective is to demonstrate the feasibility and safety of this novel procedure.

Methods

A 45-years old patient was admitted to the emergency department with a 3-day history of right iliac fossa (RIF) pain and nausea. On clinical examination there was localized peritonitis confined to the RIF. Biochemistry and imaging studies confirmed the clinical diagnosis of acute appendicitis. A laparoscopic exploration and appendectomy was performed. Peroperative findings included: perforated appendicitis with diffuse contamination of the abdominal cavity and two hard nodules on the peritoneal surface of the RIF at a distance of the appendix itself at that time interpreted as local inflammatory changes. A laparoscopic appendectomy and lavage was performed. Cultures of the abdominal fluid were negative. Post-operative stay was uneventful. Anatomopathology of resected specimen unexpectedly revealed an invasive well-differentiated appendiceal carcinoma located at the perforated top of the appendix. In retrospect the lesions on the peritoneum of the RIF were considered potential peritoneal metastases. Staging was performed by CEA, liver ultrasound, helical CT-scan and PET-scan. No evidence of distant metastasis was encountered. Repeat laparoscopy was performed after 3 weeks. Patient was positioned in modified lithotomy-position. Five Versaport 5-12mm trocars® (Tyco Healthcare Group, Norwalk, Connecticut USA) were positioned and secured at the umbilicus and in the four quadrants (figure 1). The incisions of the previous laparoscopy were deliberately avoided. An extensive laparoscopic staging of the peritoneal surface including the bursa omentalis minor using a 45°-angled scope was performed and confirmed the two suspect lesions on the peritoneum of the RIF (figure 2); the peritoneal carcinomatosis index (PCI) according to Sugarbaker was established(5). A laparoscopic peritonectomy of the RIF and right flank was performed using the coagulating hook and forceps (figure 3). Pneumoperitoneum was helpful in exposing the peritoneum for an adequate stripping. The pneumoperitoneum was then deflated, the umbilical trocar was after rinsing the incision with povidone-iodine replaced by a handassist-device (Lapdisc®, Ethicon Endo Surgery, Cincinnati USA) (figure 4). 2 abdominal irrigation circuits were established through the 4 trocars. The inflow catheters were placed in the left subphrenic space and the Douglas cavity. The outflow catheters were at the top connected to a small plastic cage to avoid sticking to viscus and thus obstructing the abdominal perfusion (figure 5). The trocars at this point were positioned vertically and attached to an Omnitract-retractor. 6 temperature probes (Sorin Biomedica) and 3 pressure transducers (Baxter) were used as monitoring devices during the HIPEC (Figure 6). Before starting the HIPEC, 5-fluorouracil (5FU) 400 mg/m² with folinic acid 20 mg/m² was administered by IV. The surgeons hand was positioned through the Lapdisc® and the abdomen was filled with heated dextrose 5% at 43°C (figure 7). The hydroperitoneum was built up to a pressure of 10mm Hg. The roller pumps were started at a flow of 1.8 l/m and through a stirring motion of the surgeons hand a uniform temperature profile of 42° C. on all probes was reached. Subsequently Oxaliplatin 460 mg/m² was added to the abdominal irrigation circuit for 30 minutes. Intra-abdominal temperature, pressure and vital signs of the patient were monitored throughout the HIPEC. After 30 minutes the perfusate was aspirated and the abdomen flushed with normal saline. By adding methylen-blue to the perfusate we could confirm an adequate exposure of all peritoneal surfaces to the perfusate. The trocars and Lapdisc® were removed and the incisions irrigated with povidone-iodine before closing (figure 8). In addition a full thickness excision of the trocar sites of the initial appendectomy was performed.

Results

The PCI assessed during staging laparoscopy was 3. Laparoscopic peritonectomy was successful and R1-resection was achieved. The duration of the whole procedure was 145 min. The target intra-abdominal temperature of 43° was achieved after 17 min. A uniform homogeneous temperature and pressure profile could be sustained during the laparoscopic HIPEC. A flow of >2l/min was recorded throughout the procedure. No leaks of irrigation fluid through trocars or Lapdisc® were noted. The perfusate was recovered without contamination in a closed circuit bag. During laparoscopic HIPEC repeated blood samples were obtained. These revealed hyperglycemia/hyponatremia which was treated with an insulin-drip. The postoperative stay was uneventful, liquids were started the evening of surgery and solid intake the next day. No wound infection was observed. Patient was discharged on postoperative day 4. A blood sample on day 7 was within normal limits. After 7 months follow up there is no evidence of recurrent disease. Anatomopathology confirmed peritoneal metastasis of the appendiceal carcinoma in the resected peritonectomy specimen. Unexpectedly viable tumor cells were encountered in one of the excision specimens of the initial trocar sites of the appendectomy.

Discussion

Until recently, peritoneal carcinomatosis of colorectal origin was considered systemic disease beyond the scope of curability. The last two decades saw the emergence of arguments in favor of considering PC as a step between local disease and systemic spread (6) and the rise of cytoreductive surgery and HIPEC as a treatment option with a curative intent. The role of laparoscopy in treating peritoneal carcinomatosis has yet to be defined. Laparoscopy HIPEC has been explored in palliation of debilitating malignant ascites with excellent successrates as to resolution of the ascites in our institution and others (7). So far laparoscopic peritonectomy and HIPEC were not attempted in a potential curative setting. Recent animal studies by Ferron et al.(4) indicated that laparoscopic peritonectomy and HIPEC could be performed safe and efficient in an animal model. There are suggestions in literature that the increased pressure during laparoscopic HIPEC might add to penetration depth of the chemotherapeutic solution (8,9). We suggest with this first clinical case-report that laparoscopic peritonectomy and HIPEC is safe and feasible in treating limited peritoneal carcinomatosis with curative intent. It is clear that extensive peritoneal involvement will never be an indication for laparoscopic peritonectomy and HIPEC. Fase I-II studies are required for further validating this technique.
Lessons learned from HIPEC in gastric surgery suggest a benefit of HIPEC in an neoadjuvant setting in high risk patients with no peritoneal metastasis at the time of curative surgery (10). In an era were laparoscopy is validated as a tool in resecting colonic and gastric malignancies; laparoscopic HIPEC might be of benefit in preventing peritoneal metastases in high risk patients (positive cytology, immunocytohistochemistry,...).

Malignant ascites is a debilitating condition affecting cancer patients in their terminal stage of disease. Recently, laparoscopic hyperthermic intraperitoneal peroperative chemotherapy (HIPEC) was introduced as a new approach. From September 2001 to August 2008, 52 patients were treated with this new modality. No treatment-related mortality was observed. Median survival was 98 days. One patient developed a clinical recurrence. Laparoscopic HIPEC is a safe and effective method for palliating malignant ascites

Heated intra-operative intraperitoneal oxaliplatin after complete resection of peritoneal carcinomatosis: pharmacokinetics and tissue distribution

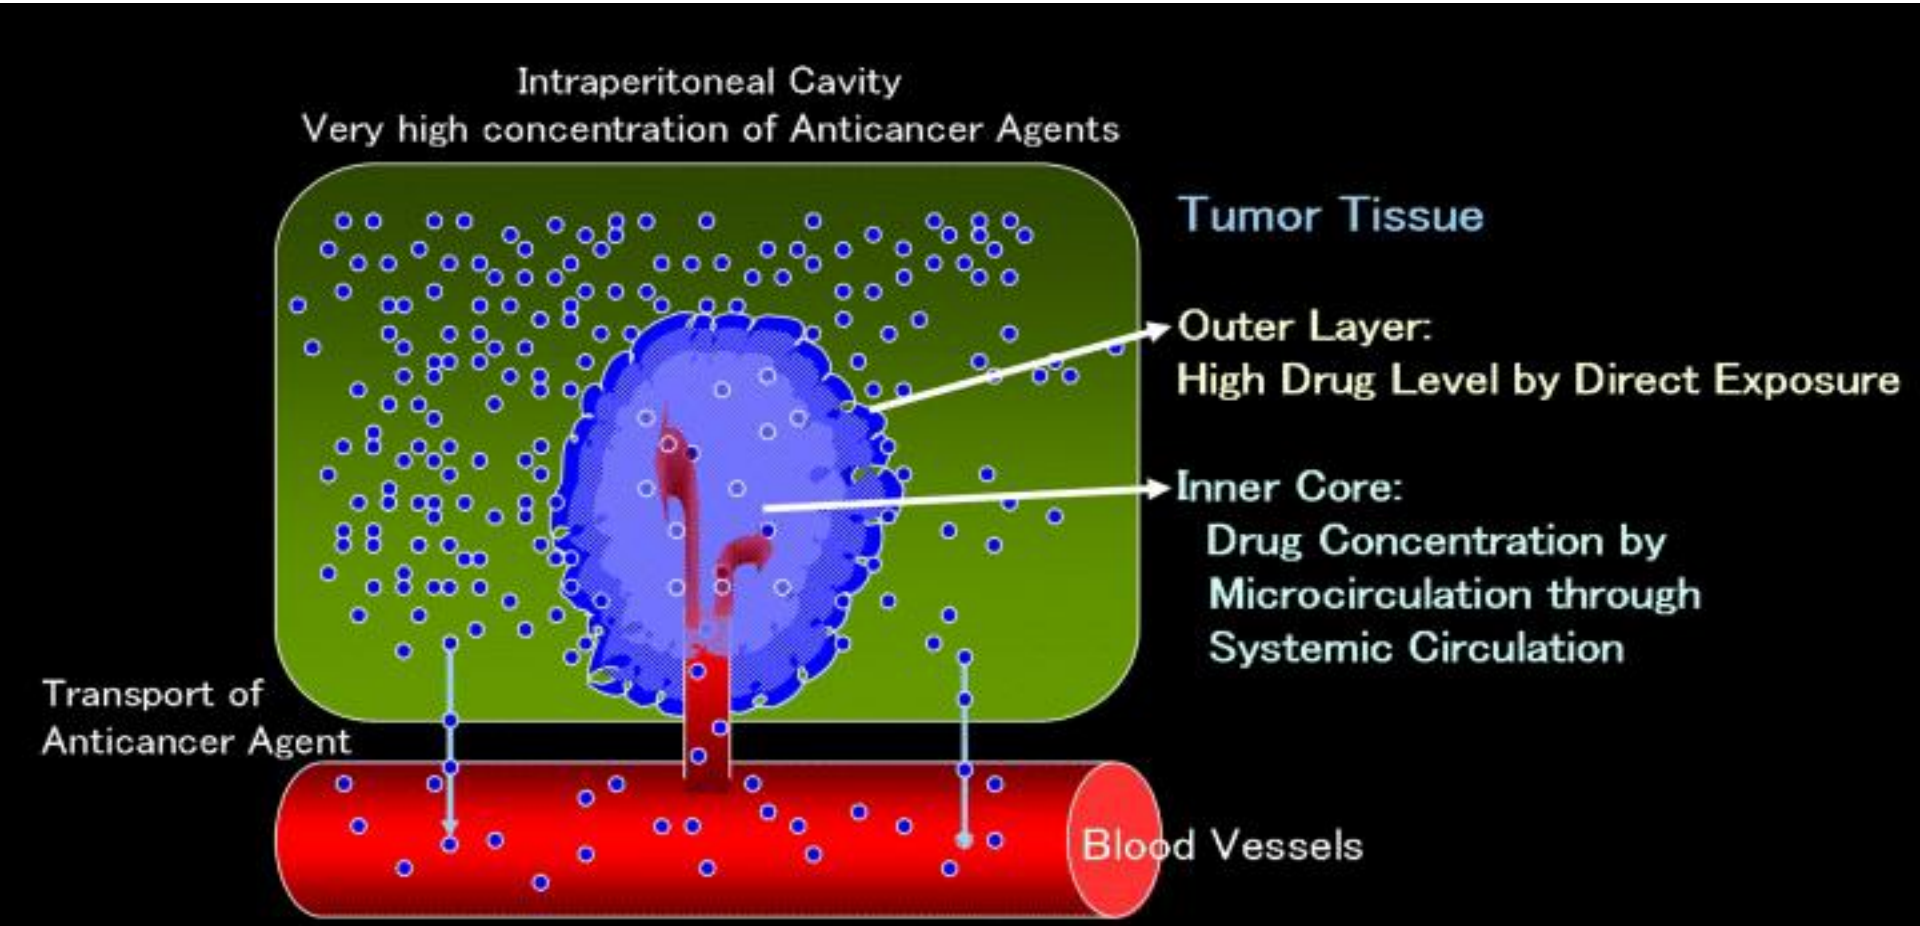
D. Elias*, M. Bonnay, J. M. Puizillou, S. Antoun, S. Demirdjian, A. El Otmany, J. P. Pignon, L. Drouard-Troalen, J. F. Ouellet & M. Ducreux

One hour before IPCH we delivered systemic intravenous leucovorin 20 mg/m^2 and 5-FU 400 mg/m^2 because 5-FU potentiates the action of oxaliplatin [11]. However, as 5-FU cannot be mixed with oxaliplatin in the peritoneal cavity due to pH incompatibility, it was delivered intravenously. Following this systemic perfusion, tumour and healthy tissue were soaked with 5-FU before the beginning of the IPCH. A low dose of 400 mg/m^2 was chosen to avoid intensifying the aggressiveness of combined complete cytoreductive surgery and IPCH.

Annals of Oncology 13: 267–272, 2002

TIMING OF PERIOPERATIVE IV CHEMOTHERAPY

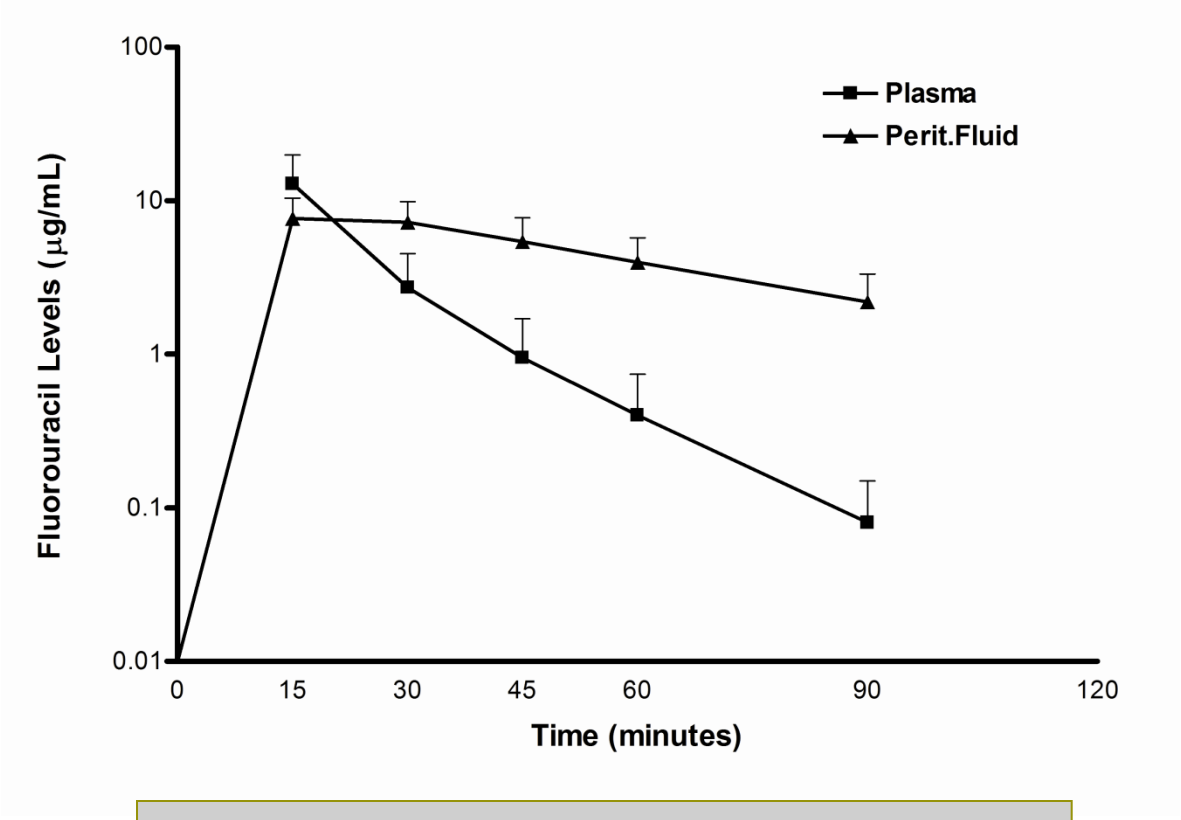
Pharmacologic concept of bidirectional (IV and IP) chemotherapy



Modified from Fujiwara K. Int J Gynecol Cancer 2007,17,1-20

TIMING OF PERIOPERATIVE IV CHEMOTHERAPY

FIGURE 2: 5-Fluorouracil concentrations in peritoneal fluid and plasma after intravenous administration during hyperthermic intraperitoneal chemotherapy procedure (N=20).



- **Rapid distribution to ALL body compartments**
- **metabolization restricted to plasma compartment**

Journal of Surgical Oncology 2010;102:730–735

TIMING OF PERIOPERATIVE IV CHEMOTHERAPY

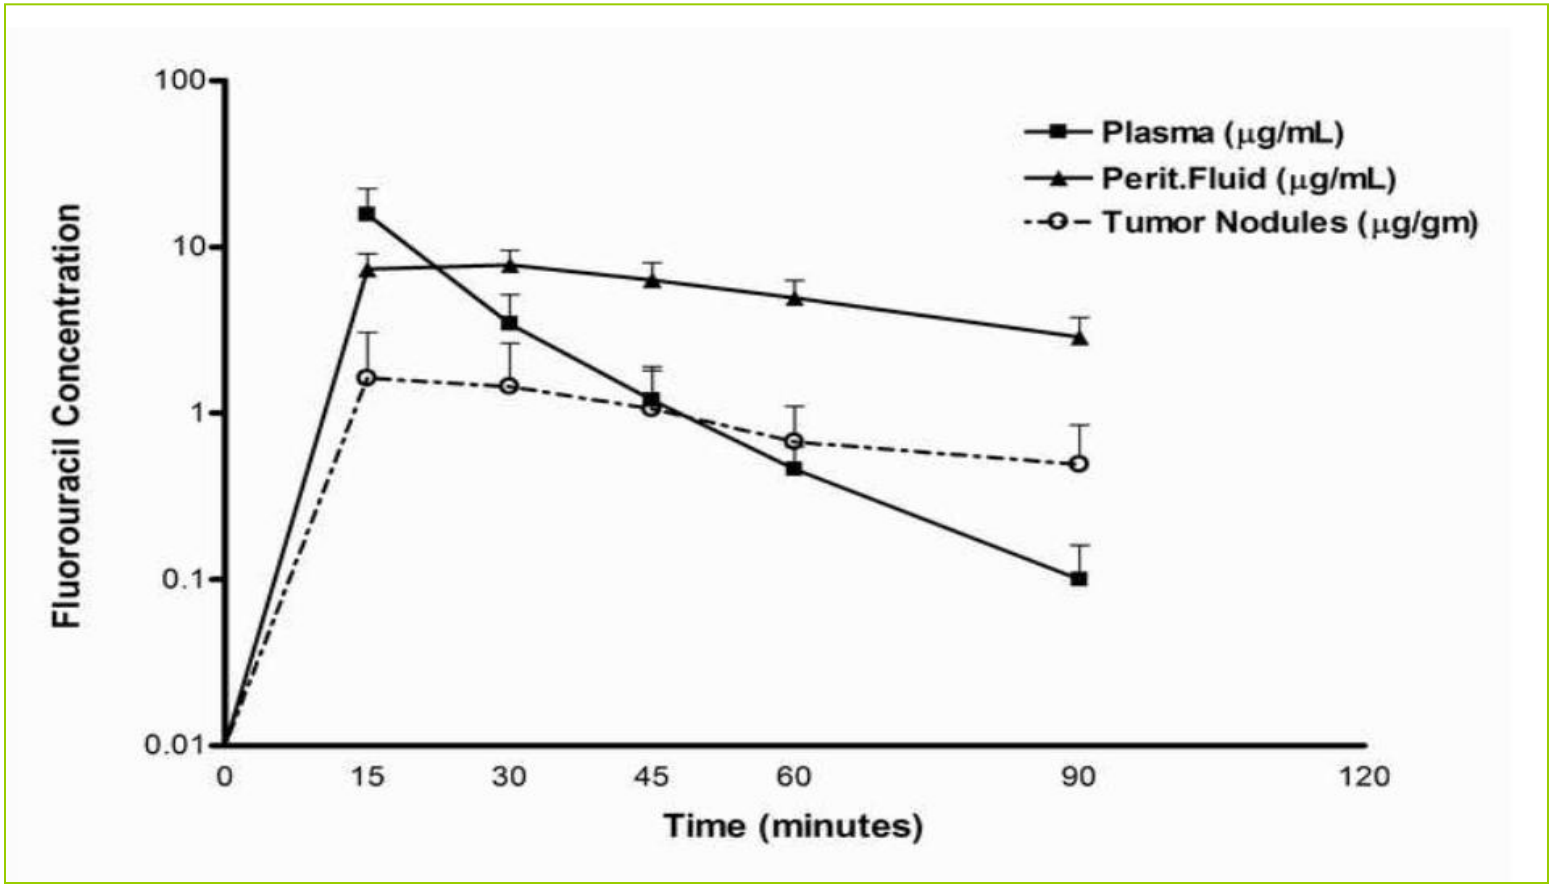


FIGURE 3: 5-Fluorouracil concentrations in plasma, peritoneal fluid and tumor nodules after intravenous administration during hyperthermic intraperitoneal chemotherapy procedure (N=9).

TIMING OF PERIOPERATIVE IV CHEMOTHERAPY

Rationale for **intravenous** administration of 5-fluorouracil *(augmentative drug)*

- Rapid distribution to all body compartments (including peritoneal cavity)
- Metabolisation confined to plasma compartment
- Pharmacokinetic advantage

Timing of intravenous chemotherapy emerges as a new variable

- Pharmacological ‘sink’ phenomenon in the artificial ascites
- Ideal situation for drug synergism with intraperitoneal chemotherapy
- Normothermic administered IV 5-FU = subject to IP hyperthermic augmentation

INDIVIDUAL

DRUG SENSITIVITY

PERITONEAL CARCINOMATOSIS : CONCLUSIONS

- PSM is a locoregional disease and as such warrants a locoregional approach.
- CRS addresses macroscopic disease and the subsequent intraperitoneal chemotherapy eliminates residual microscopic disease
- Dose intensification (IP/IV) is the driving force
- Tumor nodules emerges as the pharmacologic endpoint
- Timing of IV chemotherapy emerges as a new pharmacologic variable
- Individual drug sensitivity ?

THANK YOU
